

VIOLENCE ON THE BRAIN:
A CRITIQUE OF NEUROSCIENCE IN CRIMINAL LAW

*Amanda C. Pustilnik**

Abstract

Is there such a thing as a criminally “violent brain”? Does it make sense to speak of “the neurobiology of violence” or the “psychopathology of crime”? Is it possible to answer on a physiological level what makes one person engage in criminal violence and another not, under similar circumstances?

Current research in law and neuroscience is promising to answer these questions with a “yes.” Some legal scholars working in this area claim that we are close to realizing the “early criminologists’ dream of identifying the biological roots of criminality.” These hopes for a neuroscientific transformation of the criminal law, although based in the newest research, are part of a very old story. Criminal law and neuroscience have been engaged in an ill-fated and sometimes tragic affair for over two hundred years. Three issues have recurred that track those that bedeviled earlier efforts to ground criminal law in brain sciences. First is the claim that the brain is often the most relevant or fundamental level at which to understand criminal conduct. Second is that the various phenomena we call “criminal violence” arise causally from dysfunction within specific locations in the brain (“localization”). Third is the related claim that, because much violent criminality arises from brain dysfunction, people who commit such acts are biologically different from typical people (“alterity” or “otherizing”).

This Article first demonstrates parallels between certain current claims about the neurobiology of criminal violence and past movements that were concerned with the law and neuroscience of violence: phrenology, Lombrosian biological criminology, and lobotomy. It then engages in a substantive review and critique of several current claims about the neurological bases of criminal violence. Drawing on research and interviews with neuroscientists, this Article shows that causally localizing what we call “criminal violence” to bits of the brain is scientifically contestable and epistemologically untenable. In viewing the criminal law-neuroscience relationship through the lens of history of science, this Article hopes to offer a constructive portrait of how current neuroscience might inform criminal law discourse about regulating violence.

* Climenko Fellow & Lecturer on Law, Harvard Law School. I would like to thank Yochai Benkler, I. Glenn Cohen, Oliver Goodenough, Anne Harrington, and Martha Minow for invaluable advice and comments on drafts. I am grateful as well for the advice and comments of Drs. INTRODUCTION

Is there such a thing as a criminally “violent brain”? Does it make sense to speak of “the neurobiology of violence”¹ or the “psychopathology of crime”²? Is it possible to answer on a physiological level what makes one person engage in criminal violence and another not, under similar circumstances?

Current research in law and neuroscience is promising to answer these questions – and to answer each of them with a “yes.” Several scholars working in this area claim that we are “close[] to realizing the early criminologists’ dream of identifying the biological roots of criminality.”³ They urge not that some criminals suffer from mental diseases but that “crime [is] a disease,”⁴ that the criminal law should across the board “adopt a disease theory view of crime.”⁵ This “disease” of violent crime does not arise from metaphorically “sick” personal choices or social conditions; rather, some claim that neuroscientists have discovered in criminal offenders a “‘biological brain-proneness’ toward violence” that substantially explains the existence of violent crime.⁶

The current, hopeful claims about the discovery of biological roots of criminality are part of a very old story. Criminal law and neuroscience⁷ have been engaged in an episodic

⁷ The term “neuroscience” is of recent coinage and so is anachronistic when applied to the brain sciences of earlier eras; however, I use it throughout as a convenient umbrella term for both current and past scientific investigations of human brain structure and function.

and ill-fated love affair for over two hundred years. In each era, it starts with bold promises and a belief in the genuine mutual compatibility of the two fields, but ends in disappointment and even tragedy. With every resurgence in this mutual infatuation, lawmakers and scientists swear that they won't make the same mistakes this time – principally because this time, science has finally matured.

The fraught relationship between criminal law and neuroscience is worth re-examining now, in light of its history, because we are at a moment of renewed infatuation. Indeed, we are at the threshold of what some claim is no less than a neuroscientific revolution within law that promises biologically-based explanations of general features of human conduct.⁸ This new movement carries forward some of the suspect epistemology of the prior movements – but it also contains more real potential. A careful understanding of the epistemic traps of the past and their relationship to certain current ways of framing the brain-criminal law relationship will help integrate neuroscience with law in ways that can enhance specific doctrines within criminal law and evidence, although in a more bounded fashion than some of the movement's strongest proponents might claim.

Neuroscience evidence and principles have already begun to find their way into criminal adjudications⁹ and criminal law scholarship.¹⁰ This explosion of interest in

⁸ See, e.g., Semir Zeki & Oliver R. Goodenough, *Law and the Brain: An Introduction*, 359 *PHILOS. TRANS. R. SOC. LOND.* 1661, 1661 (2004) (calling development of neurolaw an all but “ineluctable consequence of the current assault on the secrets of the brain.”).

⁹ To date, neuroscience evidence primarily has been offered by the defense in mitigation at sentencing. See, e.g., *People v. Page*, 186 P.3d 395, 413-14 (Cal. 2008) (in appeal of capital sentence, discussing defendant's proffer of MRI evidence showing cyst in temporal lobe and numerous brain lesions); *People v. Kraft*, 5 P.3d 68, 98 (Cal. 2000) (describing introduction of PET scan as mitigating evidence showing defendant's brain abnormalities); *Mashburn v. State*, --- So.2d ---, 2008 WL 1838313, *2 (Ala. Cr. App. 2008) (discussing lower court's provision of funds to capital defendant for MRI evaluation of defendant's brain; holding lower court's consideration of MRI evidence of no brain abnormality as probative of appropriate weighing of all evidence in sentencing); *United States v. Polouizzi*, 549 F. Supp. 2d 308, 325-26 (E.D.N.Y. 2008) (allowing admission at trial in child pornography case MRI evidence of defendant's alleged brain abnormalities); *Mosely v. Quarterman*, No. 3:03-CV-1577-N, 2008 WL 656887, *18 (N.D. Tex. Mar. 6, 2008) (in habeas appeal of capital sentence, rejecting defendant's ineffective assistance of

neuroscience to illuminate the (presumably universal) workings of the human mind has spawned a host of neuro-fields – from neuroethics,¹¹ neuroeconomics,¹² and neurohistory,¹³ to neurolaw¹⁴ and neurojurisprudence.¹⁵ Contributions to law from these emerging, hybrid fields may be substantial. Neuroeconomics, in concert with behavioral economics, is constructing more realistic and robust models of individual, group, and market behavior, with potentially profound implications for the design of legal institutions.¹⁶ The neuroimaging of pain may influence legal

counsel claim predicated on counsel’s failure to identify defendant’s “frontal lobe impairment”); *People v. Holt*, 937 P.2d 213, 231 (Cal. 1997) (admitting PET and EEG scans in mitigation in capital case); *Rogers v. State*, 783 So. 2d 980, 998-99 (Fla. 2001) (upholding trial court’s grant of funds for MRI scan for defendant’s mitigation case); *Hoskins v. State*, 735 So. 2d 1281, 1281 (Fla. 1999) (vacating death sentence for trial court’s failure to allow PET scan as mitigating evidence).

¹⁰ Since 2000 alone, over 200 articles have appeared in law reviews on the subject of criminal law and neuroscience, ranging from neuroscience-based explanations for the persistence of retributivism, see Morris B. Hoffman, *Rediscovering the Law’s Moral Roots*, 103 NW. U. L. REV. COLLOQUY 13 (2008), to arguments for raising the age until which the criminal system will treat an offender as a juvenile, see Richard F. Walsh, *Raising the Age for Juvenile Jurisdiction in Illinois: Medical Science, Adolescent Competency, and Cost*, 39 LOY. U. CHI. L.J. 767 (2008). A small sample of notable works in this very broad area includes, e.g., Stephen J. Morse, *Determinism and the Death of Folk Psychology: Two Challenges to Responsibility from Neuroscience*, 9 MINN. J. L. SCI. & TECH. 1 (2008); O. Carter Snead, *Neuroimaging and the “Complexity” of Capital Punishment*, 82 NYU L. REV. 1265, 1287 (2007); Morris B. Hoffman, *The Biological Roots of Punishment*, 1 OHIO ST. J. CRIM. L. 627 (2004); Martha J. Farah & Paul Root Wolpe, *Monitoring and Manipulating Brain Function: New Neuroscience Technologies and their Ethical Implications*, 34 HASTINGS CTR. REP. 35 (2004); Joshua D. Greene & Jonathan D. Cohen, *For the Law, Neuroscience Changes Nothing and Everything*, 359 PHIL. TRANSACTIONS OF THE ROYAL SOC. OF LONDON B (Special Issue on Law and the Brain), 1775 (2004); Zeki & Goodenough, *supra* note 9.

¹¹ See, e.g., MICHAEL S. GAZZANIGA, *THE ETHICAL BRAIN: THE SCIENCE OF OUR MORAL DILEMMAS* (2006) [“GAZZANIGA, ETHICAL BRAIN”] (defining neuroethics as the study of the relationship between ethical reasoning and in-built brain mechanisms or patterns; arguing that there is a universal ethical template built into the brain); cf. DAI REES & STEVEN ROSE, *NEW BRAIN SCIENCES: PERILS AND PROSPECTS* (2004) (arguing that while people self-evidently use their brains for ethical reasoning, the content of ethical judgments is not biologically encoded into people’s brains). Several prominent universities have founded centers for neuroethics (see, e.g., <<<http://neuroethics.upenn.edu/>>>) and there is a widely-read Neuroethics & Law Blog (see <<<http://kolber.typepad.com/>>>).

¹³ DANIEL LORD SMAIL, *ON DEEP HISTORY AND THE BRAIN* (2007) (arguing that the field of history should be expanded to include “neurohistory”; Smail contends, generally, that aspects of human prehistory can be divined from the structure of, and inheritance evidenced by, our brains).

¹⁴ Jeffrey Rosen, *The Brain on the Stand*, N.Y. TIMES MAGAZINE, Mar. 11, 2007 (coining “neurolaw” to describe uses of neuroscience in lawmaking and in legal doctrine).

¹⁵ Redding, *supra* note 3, at 53 (arguing that the criminal law must develop “neurojurisprudence” to account for knowledge being developed in the brain and cognitive sciences).

¹⁶ Among many other fine works, see, e.g., Claire A. Hill & Erin Anne O’Hara, *A Cognitive Theory of Trust*, 84 WASH. U. L. REV. 1717 (2006) (applying cognitive and behavioral theories of “optimal trust” to the design of legal institutions); PAUL W. GLIMCHER, *DECISIONS, UNCERTAINTY, & THE BRAIN: THE SCIENCE OF NEUROECONOMICS* (2003); Paul J. Zak, *Neuroeconomics*, in *LAW AND THE BRAIN* 133-53 (Samir Zeki & Oliver Goodenough eds.,

doctrines from tort and disability to the death penalty and torture.¹⁷ And work on the relationship between emotion and decision-making may cause legal scholars and philosophers to re-examine the relative importance of, and relationships between, emotional and reason-based methods of decision-making.¹⁸

Moving far beyond that, however, some important voices make more imperialistic claims, arguing that we will be able to craft social regimes built on “universal morals possessed by all members of our species, ... a brain-based philosophy of life.”¹⁹ It is the contention of this Article that overreaching claims about the relationship between individual neurobiology and criminal violence can undo the productive contributions that neuroscience could otherwise make to the criminal law. Because such claims exceed what the data show, early legal adopters of more extreme forms of “neurolaw” could create a backlash against neuroscience findings. Perhaps most importantly, they may lead to misapplications similar to those of prior episodes of the criminal law-neuroscience story.

The central tenets of some current work on the criminal law and neuroscience of violence are similar to those that underlay, and ultimately undermined, past movements. This Article will argue that these tenets, and the problems inherent in them, are:

2006); Dan M. Kahan, *The Logic of Reciprocity: Trust, Collective Action, and the Law*, in MORAL SENTIMENTS AND MATERIAL INTERESTS: THE FOUNDATIONS OF COOPERATION IN ECONOMIC LIFE 339 – 78 (Herbert Gintis et al. eds., 2005).

¹⁷ See, e.g., Amanda C. Pustilnik, *Seeing Pain, Measuring Value(s): Neuroimaging Pain from Tort to Torture* (in progress) (collaborating with neuroscientists to explore legal consequences of pain imaging); Adam J. Kolber, *Pain Detection and the Privacy of Subjective Experience*, 33 AM. J.L. & MED. 433 (2007) (arguing for use of neuroimaging evidence of pain in litigation). The notion of the chronic pain patient as suffering from “conversion hysteria” or “accident neurosis” may be largely undone by advances in identifying neural mechanisms of pain chronification, putting to rest one of the last golems of Freudianism in the law. Hank Greely and Stephen Morse also are exploring the relationship between pain neurobiology and law in forthcoming work.

DRAFT – NOT FOR QUOTATION; COMMENTS INVITED

- Because all behavior emerges from the brain, the individual brain, in isolation, is the most relevant site for understanding criminal behavior (this presents the problem of levels of explanation);
- Because the brain is composed of specialized regions, criminal behaviors like unlawful violence of all kinds must arise from particular brain regions (this presents the compound problem of reification and localization), and;
- Because some people who commit violent crimes have brain disorders, lawbreaking is best understood as the result of disease or as a disease in itself (this is the problem of alterity or “otherizing”).

In viewing the criminal law-neuroscience relationship through the lens of history of science, this Article hopes to offer both caveats and a constructive portrait of how neuroscience might inform criminal law discourse on regulating violence without recapitulating these issues.

Part I of this Article, A History of Violence, examines three movements in law and brain science that prefigure and inform current efforts: phrenological studies of criminal behavior in the late 18th and early 19th centuries, Cesare Lombroso’s “scientific” criminology in the late 19th and early 20th centuries, and psychointervention (lobotomy and electrode implantation) arising against the backdrop of social turmoil of the mid-20th century. In each of these subsections, I will show how these disparate (although equally ill-fated) attempts to solve the problem of violent crime through then-current brain sciences evolved similarly: Each started out with a pre-commitment to the idea of the brain localization of violence, often based on studies either of extreme human pathology or studies of animals with substantially different evolutionary histories than humans. The scientific and medical proponents of each had an express interest in the social implications of their work and sought to reform or revise criminal law through their work. And, legal scholars and criminal law actors embraced and put into practice regimes based on the work before an ultimate backlash shut them down.

DRAFT – NOT FOR QUOTATION; COMMENTS INVITED

The tragic shortcomings of the work of earlier eras now are dismissed as unfortunate historical curiosities.²⁰ This Part will contend, however, that past efforts to invent a scientific criminal law based on brain science foundered on many of the same shoals that could undermine current neurolaw efforts; the history of these failures thus provides a highly relevant set of lessons.

Moving from historical to current efforts to ground criminal law in brain science, Part II describes examples of current scholarship on the neurobiology of violence. It presents arguments of influential scholars that there is a deterministic relationship between violent behavior and what they identify as brain dysfunction. Such scholars embrace the view that the “mechanistically determined” brain contains “the essential ingredients of the human condition.”²¹ This Part also will examine causal claims made from neuroimaging studies through examining an exemplary study on brain differences between pedophiles and typical adults. Because scholarship described in this Part emphasizes the biology of individual brains above other modes of explaining criminality, it emerges from the tradition of reductionism in Western scientific and philosophical thought. A full-scale critique of reductive individualism in legal uses of brain sciences is beyond the scope of this paper. However, this Part will set up the Article’s consideration of the “practical, technical, and epistemic concerns”²² posed by such brain-based reductionism in criminal law.

Part III shows the formidable, perhaps insurmountable, technical and epistemic hurdles to a purely, or primarily, brain-based view of violent crime. Critiquing current claims

²⁰ Brent Garland & Mark S. Frankel, *Considering Convergence: A Policy Dialogue About Behavioral Genetics, Neuroscience, and Law*, 69 SPG LAW & CONTEMP. PROBS. 101, 109 (2006) (calling prior efforts to integrate brain sciences with criminal law through, e.g., phrenology and lobotomy, “misguided” because they were based on “immature science”).

²² Snead, *supra* note 10, at 1287.

within legal scholarship about the neurobiology of violence, it demonstrates the major barriers to the causal localizability of violence to specific parts of the brain (particularly, the prefrontal cortex²³ and the amygdala²⁴). This Part looks first at the state of knowledge in neuroscience about the localizability of brain function generally, starting with sensory-motor localization. It then presents the major challenges that other neuroscientists have raised in relation to attempts to localize higher cognitive functions and behaviors, like “violence.” Finally, it considers an in-principle barrier to reducing violence entirely to brain operations: The role of law in defining what is or is not “violence.” Given that the law can and does change what is encompassed within the category of violence, unlawful violent behavior must be understood at least in part as arising relationally between people and the law, rather than entirely internally to the brain.

The final Part draws out the conceptual and epistemological commonalities among current and historical criminal law efforts to understand violence neurobiologically. It will argue that past and current efforts to develop a purely brain-based understanding of violence in criminal law manifest certain epistemological problems. While contemporary researchers now use sophisticated techniques to image or stimulate parts of the brain, today’s claims that a general cause of violence is overactivity or hypometabolism in certain brain regions are not conceptually distinct from lobotomists’ claims that violence could be cured through cutting out the violent part of the brain²⁵ or phrenologists’ assertion that there is a “murder bump.”

Moving to the potential uses of neuroscience in the criminal law, it will contrast the legal applications of neuroscience that would emerge from the view that violent conduct is

²³ The prefrontal cortex comprises the “associational” part of the frontal lobes of the brain. The frontal lobes contain motor and associational areas. The motor areas are involved in the initiation of skilled motor activities; the associational areas are involved in “distinctly human” activities including planning, memory, problem solving, and social conduct. THOMAS C. PRITCHARD & KEVIN D. ALLOWAY, *MEDICAL NEUROSCIENCE* 199 (1999). The many functions of the pcf are discussed further, *infra*, at nn. 192 - 202, and accompanying text.

²⁴ The amygdala is a small structure deep in the brain that is believed to play a role in regulating emotion. *Id.* at 174.

²⁵ Amygdalotomy is a type of psychosurgery (lobotomy) in which the surgeon excises or destroys the amygdala.

the expression of brain dysfunction versus those that would emerge from a view that the brain is an important, but not exclusive, level of explanation for different types of violent crimes. The former approach is strongly individualistic; its prescriptions would focus on finding and treating some disorder within the offender’s brain. The second approach would also account for medical pathology, if any. But, in viewing the brain as a contributor to and a product of the social world, and in viewing violence as a set of behaviors that are not *per se* pathological, this approach points toward using neuroscience as one tool to help understand an array of issues of relevance to the criminal law, including – among other issues – how people make decisions about obeying or breaking the law; what conditions provoke violence in typical as well as atypical people; and the general conditions (such as minimum early childhood needs) for developing healthy, well-functioning minds.

I. A HISTORY OF VIOLENCE (IN CRIMINAL JURISPRUDENCE)

The criminal law takes as its object the definition, deterrence, and punishment of proscribed violent behavior; indeed, the regulation of interpersonal violence (and the arrogation to the state of the prerogative to inflict violence) arguably is a primary focus of criminal lawmaking and theory.²⁶ So explanations of the causes of – and potential ways to identify and address people prone to – violence are, at least in theory, of great criminal law significance. Accordingly, theories of the causes of violence and of ways to identify and deal with people who may be prone to violence historically have exerted tremendous pull over many criminal law

²⁶ See, e.g., DAVID GARLAND, PUNISHMENT AND MODERN SOCIETY: A STUDY IN SOCIAL THEORY 69-81 (1990) (discussing Durkheim’s view of the criminal law as institutionalized vengeance); James Q. Whitman, *Between Self-Defense and Vengeance/Between Social Contract and Monopoly of Violence*, 39 TULSA L. REV. 901, 922-23 (2004) (discussing the “the monopoly of violence theory” as a compelling “account of the purposes of criminal law”); Martha Minow, *Redressing Mass Violence*, in THE PASSIONS OF THE LAW 265, 265 (Michael Crozier et al. eds., 1999) (“The institution of criminal justice in liberal societies ... transfers the authority and power to respond to private violence from the victim ... to the state[.]”).

scholars and practitioners. “We are placing the question of violence right in the middle of our basic research on the neurobiology of emotion,” says clinical psychologist Richard Davidson.²⁷

This Part looks at several examples of historical efforts to tackle violence scientifically within law: phrenological studies of criminal behavior in the early 19th century, Cesare Lombroso’s “scientific” criminology in the late 19th and early 20th centuries, and psychosurgery and subsequent, related efforts on the neurobiological control of violence arising in part out of mid-20th Century US race riots. This history of these failed scientific approaches to violence in the criminal law highlights general methodological and epistemological traps; it thus provides a highly relevant and instructive set of lessons. The sometimes uncanny similarities between past and current efforts also provide a useful counterbalance to the current untempered enthusiasm for “neurolaw” solutions to problems of violence.

A. The Original Scientific Criminologies

*1. Phrenology: You Should Have Your Head Examined*²⁸

Phrenology was the nineteenth century’s science of the mind. Scientists and doctors who practiced phrenology, starting with the Austrian anatomist Franz Josef Gall, contended that a person’s character could be determined from the bumps and hollows on the outside of the skull.²⁹ From the beginning, Gall’s work intersected with the criminal law, as he principally developed his observations and theories through examining the heads of criminals

²⁷ Brian Mattmiller, *Brain Study Sheds Light on Impulsive Violence*, UNIVERSITY OF WISCONSIN-MADISON NEWS (July 27, 2000) (interview with Richard Davidson) (also available through ScienceDaily <<<http://www.sciencedaily.com/releases/2000/08/000814021300.htm>>>).

²⁸ AMERICAN HERITAGE DICTIONARY OF IDIOMS 239 (1997) (the expression “to get one’s head examined” is “thought to allude to ... phrenology”; probable origin in “early 1900s”).

²⁹ MADELINE B. STERN, HEADS AND HEADLINES: THE PHRENOLOGICAL FOWLERS X (1971) (describing Gall’s role in originating the science of phrenology). See also JOHN D. DAVIES, PHRENOLOGY: FAD AND SCIENCE 6-7 (1955) (describing phrenology); Pierre Schlag, *Law and Phrenology*, 110 HARV. L. REV. 877, 880 (1997) (same).

and those confined for insanity.³⁰ Specific bumps and depressions were said to correspond to qualities like “wit, joking,” and “poetic ability.”³¹ Others corresponded more closely to the study of violent crime: and “instinct to kill,”³² “combativeness,” and “destructiveness.”³³ All was not lost, though, if your skull revealed you to be, for example, hopelessly humorless (or murderous): You could increase the size of your brain’s funny bone, as it were, through the right sorts of exercise, changing both your character, your brain, and (presumably) the shape of your skull.

Fashionable citizens flocked to phrenologists to have their “heads examined” – with decidedly mixed results. Samuel L. Clemens (better known as Mark Twain) visited a prominent phrenologist in 1873, under another assumed name.³⁴ The good doctor discovered something remarkable about his anonymous patient: A “total absence of the sense of humor.”³⁵ Three months later, the same phrenologist was delighted to welcome a very famous new patient: Mark Twain. During the examination of *Mr. Twain*, the phrenologist discovered a “Mount Everest of a bump of humor.”³⁶

Twain’s experience with phrenology was innocent fun, but phrenology had serious impact on the criminal law in the United States and Europe. Phrenology informed

³⁵ *Id.* (quoting the phrenological doctor).

³⁶ *Id.* (internal punctuation omitted).

criminal law reform proposals,³⁷ jurists used phrenology to separate the criminal from the insane, and to provide reliable ways to identify both;³⁸ expert phrenology testimony was introduced in mitigation at sentencing;³⁹ and the founder of forensic psychiatry embraced phrenology as a way of showing the trier of fact the relationship between brain and behavior.⁴⁰

“Prophylactic” phrenology was proposed to determine who might be a risk for criminal behavior in the future.⁴¹ Indeed,

police departments claimed to put this theory into practice, training their detectives to arrest ‘criminal types’ – who had not yet to their knowledge committed any crime – on sight. ‘Keen observers have over and over again marked and arrested apparently inoffensive rogues, whom they had never seen before in person or in pictures’[.]⁴²

Phrenology also influenced the McNaughten test for insanity; that test’s separation of the ability to know right from wrong from the rest of the accused’s state of mental disease reflects the phrenological notion of distinct mental “organs,” in significant contrast to other, more integrative views of mind and mental disorder.⁴³

Judges turned to phrenology to determine the sanity of murders (and for many civil uses, as well, such as ascertaining the capacity of testators and witnesses).⁴⁴ In *Ferrer v. State*, for example, an 1853 murder case, the Ohio Supreme Court turned to phrenology in considering whether a housekeeper could be held criminally responsible for poisoning a young

boy.⁴⁵ The judge wrote that the housekeeper was “remarkably ugly.”⁴⁶ All but diagnosing her from the bench, the judge noted that a phrenologist would just have to look at the shape of her head to know she was criminally insane, with murderous impulses.⁴⁷

Another judge, in an 1840 civil case concerning the capacity of a testator, spoke for the pervasive influence of phrenology on legal culture when he stated that:

[N]o man having any regard for his reputation in medical science would dispute that the brain ... consist[s] of distinct organs, each having a distinct function, and that power of function is influenced by organic size.⁴⁸

Yet, by the mid-1900s, phrenology, this “true science of the mind” that had influenced criminal laws, criminal and civil trials, and the course of peoples’ lives, had the status of a joke. Not only was phrenology discarded as a tool of justice – much less the path to “Perfect our Republic ... [and] Reform The World.”⁴⁹ But rather, it was banned in many U.S. jurisdictions alongside “fortune telling” and “astrology.”⁵⁰ In recent jurisprudence, phrenology has been classed with “voodoo.”⁵¹

This spectacular fall from grace came in the normal way: Scientists challenged phrenology internally to science, while social theories about the nature of the mind – particularly with the advent of Freudian psychoanalysis in the early 20th century – challenged it externally, ultimately resulting in an integrative paradigm of mind with no place for fixed “brain organs.”

As early as 1838, neuroanatomists had shown that the brain did not have enough discrete regions

Gipson*, 24 M.J. 246, 249 (1987) (describing the hierarchy of scientific evidence, stating that “[a]t the bottom lies a junk pile ... so universally discredited that a trial judge may safely decline even to consider [its contents], as a matter of law. To that level have been relegated such enterprises as phrenology, astrology, and voodoo.”).

to support the claim that all major personality traits could arise from specialized brain organs.⁵² Many showed, as well, that the various parts of the brain need to work in concert to produce most types of actions.⁵³ Further, it became clear – over much social contestation, particularly about race and sex – that brain size (and the size of parts of the brain) bear no clear relationship to aptitude,⁵⁴ and that people could retain particular traits or abilities when the part of the brain in which the trait allegedly resided was destroyed by illness or injury.⁵⁵

If phrenology’s approach to the relationship between brain structure and character sounds unscientific, or even silly, pause: It is very close in certain respects to modern approaches. Phrenologists identified the biology of particular parts of the brain as the most relevant level of explanation for character and behavior – a person is a killer or a humorist based on his brain’s configuration. This makes the individual brain the most (perhaps the sole) relevant consideration in determining whether a person has a criminal nature. Further, it turns actions that people do into statuses of what they are; a person who engages in a violent criminal act does so because he *is* a biological criminal, someone physically different from law-abiding people.

Although “phrenology ultimately failed as a science,” and lives as the pseudo-science *par excellence* in the public and judicial imagination,⁵⁶ “it left behind a formalized concept of cerebral localization” of complex behaviors and of root biological difference between law-breaking and law-abiding people.⁵⁷ This way of thinking about brain structure and its

relationship to criminality left the door open to the notion that “a science not too different from ... phrenology could be used” to investigate putative biological difference between people who commit criminal acts and others.⁵⁸ That legacy soon would be picked up by a young doctor whose *zeitgeist* included phrenology, Cesare Lombroso.

2. *Lombrosian Biological Criminology*

Shortly after the demise of phrenology, “biological criminology” (or “criminal anthropology”)⁵⁹ sprang from the brain of a criminal. When Cesare Lombroso was a young doctor at the asylum in Pavia, he was asked to conduct a post-mortem on an infamous serial rapist and murderer. Opening the criminal’s skull to reveal his brain, Dr. Lombroso had an insight “like a flash of light.”⁶⁰ He claimed to have found numerous abnormal features of the brain (as well as the skull), including an enlargement of the cerebellum⁶¹ “like that found in the lower types of apes, rodents, and birds.”⁶² In this moment, from this brain, Lombroso formed his famous theory of atavistic criminality – that is, that criminality results from a person having a “throw-back” brain to something lower than the “primitive races”; indeed, back to the “carnivores.”⁶³ Although biological criminology later embraced other “atavistic” features of “born criminals” that linked them to the “primitive races” (such as longer forearms and,

⁵⁸ Tovino, *supra* note 37, at 207.

⁵⁹ For a history of this movement, see DAVID G. HORN, *THE CRIMINAL BODY: LOMBROSO AND THE ANATOMY OF DEVIANCE* (2003) (excellent general history both of Lombroso’s work and of the development and influence of the school of criminal anthropology).

⁶¹ The cerebellum is a structure at the base of the brain involved in basic voluntary motion, such as the unconscious regulation of gait and motion, and the integration of sensory information to facilitate motion. PRITCHARD & ALLOWAY, *supra* note 23, at 332.

⁶² *Id.* at 38.

⁶³ *Id.*

absurdly, “the prehensile foot”),⁶⁴ it is the head of the criminal – the house of the “criminal mind” – that gave rise to the biological criminology movement.

In her well-known treatise *Criminal Man*, Gina Lombroso-Ferrero (Cesare’s daughter) wrote of the biological differences between criminal and noncriminal individuals, emphasizing differences in the head and “psychic [mental] and sensitive [nervous system] functions.”⁶⁵ Leaving no doubt about her view of the origins of these differences, she entitled her central chapter “The Born Criminal.”⁶⁶ In it, she writes that the “Modern, or Positive, School of Penal Jurisprudence” maintains that people become criminals as a result of their atavistic “psychic organization,” which “differs essentially from that of normal individuals”; indeed, criminals’ brain structure and nervous systems “strongly resemble primitive races [sic].”⁶⁷

Lombroso’s claims that criminals have atavistic brains sparked a craze for brain dissection.⁶⁸ Generally, the results of these dissections proved disappointing: They did not confirm any systematic differences in the gross anatomy of violent criminals’ brains relative to those not convicted of criminal offenses.⁶⁹ But Lombroso and his followers were not dissuaded by these facts: While they acknowledged that the abnormalities Lombroso described in his first

⁶⁴ *Id.* Note that the features Lombroso and his followers identified as atavistic characteristics of criminals were not, in fact, found upon physical examination of criminals. In their desire to see criminals as akin to the lower “carnivores,” Lombroso and others asserted that born criminals had long, fierce canine teeth and “cheek pouches,” in addition to the prehensile foot. GOULD, *supra* note 54, at 118 (discussing forearm ratios); *see also id.* at 159 (on the prehensile foot).

⁶⁸ Robert Fletcher, President, Anthropological Society of Washington, The New School of Criminal Anthropology, Address Before the Anthropological Society of Washington (April 21, 1891), in AM. ANTHROPOLOGIST 1, 20-2 (July, 1891) (summarizing brain dissection work of noted anthropological criminologists; describing results). For a general introduction to Lombroso’s work, *see, e.g.*, CESARE LOMBROSO, CRIME: ITS CAUSES AND REMEDIES (Henry P. Horton ed. & trans., 1911) (1899); *see also* Marvin Wolfgang, *Cesare Lombroso, 1835-1909*, in PIONEERS IN CRIMINOLOGY 232, 246-57 (Hermann Mannheim ed., 2d ed. 1972) (1955) (describing Lombroso’s work on the putative physical abnormalities of convicted criminals).

⁶⁹ Fletcher, *supra* note 68, at *id.*

specimen were not present in “other degenerates,” different brain abnormalities nevertheless were “prevalent in criminals.” The absence of any consistent correlations between structural brain defects and criminality seemed to reflect only that the brain is “a very recalcitrant organ [that] gives us an infinite deal of trouble when we attempt to establish positive relations between its substance and the operations of the faculties of the mind[.]”⁷⁰

The failure of brain dissection to confirm systematic differences between criminals and noncriminals tempered some claims by Lombrosians. However, they did not retreat from claims about brain differences related to violence. Gina Lombroso-Ferrero acknowledged that “lesser criminals” may not possess atavistic brains; yet, those who commit “peculiarly monstrous” crimes, like murder, nearly always demonstrate the “atavistic” brains of animals.⁷¹ There is no evidence that the brain dissections of this era did produce findings of structural brain differences between perpetrators of violent crimes versus nonviolent crimes (or of noncriminals); yet, the insistence on physical differences violent criminals’ brains seemed particularly “sticky,” difficult to dislodge in light of countervailing evidence.

Lombrosian biological criminology reveals fascinating parallels to contemporary claims about the neurological bases of violent crime. Today’s assertion that “crime [is] a disease”⁷² flowing from disordered “neurobiology” echos the claims of early 20th century biological criminologists like L. Hamilton McCormick, who asserted, “Crime is ... pathological”; it is “pathological, as it is owing to morbid affections of the brain that men frequently adopt crime as a profession.”⁷³ Placed side-by-side without citations, a reader would have difficulty distinguishing the Lombrosian statement from the new neurolaw statement – one

⁷⁰ *Id.* at 22.

⁷² Kirchmeier, *supra* note 4, at 631.

⁷³ L. HAMILTON MCCORMICK, *CHARACTEROLOGY: AN EXACT SCIENCE* 560 (1920).

claims that “crime [is] a disease” and the other that “crime is ... pathological”; one says it flows from “neurobiology,” and one says it flows from the “brain.” The current view is that violence emerges from disorders of the prefrontal cortex, which is said to regulate executive function and judgment; the nineteenth century criminal anthropologists claimed a relationship to deficits in the “the antero-superior district of the brain,” roughly equivalent to the pfc, “which betokens morality and trustworthiness[.]”⁷⁴

If the ghosts of Lombroso were those of mere bad science – faulty data or superseded hypotheses – we could look back but fleetingly at the specter. But it signifies more. Lombroso is a synecdoche for the hope that a biological criminology is possible, that the laws of man can yield to the laws of science. A contemporary critic of biological criminology (or “criminal anthropology”) spoke to its shortcomings in language that could apply equally to the neurolaw of today, saying that the field:

[O]ccupies the debatable ground between science and philosophy. As a science, it is positive and aggressive. As a philosophy, it consists almost wholly of negations, the chief of which are the negation of spirit, of freedom of the will, and of moral responsibility.⁷⁵

B. Listless Monkeys & Raging Bulls: 20th Century Psychointervention

1. Psychointervention’s Promise to Cure Violence

While biological criminology fell into disrepute, like phrenology before it, it nevertheless helped spawn the next set of tragic errors in the relationship between criminal law and brain science: Direct brain interventions against the putative neurobiology of violence. In the tumultuous middle of the twentieth century, it seemed that “[h]uman violence [was] the most threatening problem in our world.”⁷⁶ But the so-called violence problem, fortunately, appeared

⁷⁴ *Id.* at 563.

⁷⁶ VERNON H. MARK & FRANK R. ERVIN, VIOLENCE AND THE BRAIN 1 (1970).

“solvable” – through the miracles of psychosurgery (lobotomy)⁷⁷ and electrode implantation.⁷⁸

This enthusiasm for psychointervention carried forward beliefs about the brain as the best level on which to address criminality, the localization of violence to specific parts of the brain, and about the biological differences between people who do and do not commit violent crimes.

These continuities between mid-century psychointervention and prior criminal law-brain science movements are not only thematic but actually historical: Psychosurgery’s earliest founder, Gottlieb Burckhardt, drew his inspiration directly from the claims of innate brain difference advanced by Lombrosian criminology and phrenology. Reasoning that “our psychological existence is composed of single elements, which are localized in separate areas of the brain,” Burckhardt believed that he could literally “extirpat[e]” unwanted behaviors by removing specific portions of the brain.⁷⁹

In 1891, Burckhardt tested this idea by removing the cerebral cortices⁸⁰ of six people confined in his asylum in Prefargier, Switzerland.⁸¹ His results were poor (one patient

⁷⁷ There are several terms for surgical interventions in the brain aimed at modifying behavior. While the term “lobotomy” has the greatest common currency, it actually refers to one specific type of brain surgery, excision or destruction of a portion of the brain’s frontal lobes – hence, “lobe – otomy.” Other terms for brain surgeries aimed at changing mood or behavior (rather than correcting a medical pathology) include psychiatric neurosurgery, mental surgery, functional neurosurgery, sedative neurosurgery, and psychosurgery. See Stephan L. Chorover, *The Pacification of the Brain*, 7 *PSYCHOLOGY TODAY* 59, 59 (May 1974). This type of surgery is not “directed at treating specific kinds of neuropathology (e.g., tumors and strokes) or disorders of movement (e.g., tremors and paralysis).” *Id.* I use “psychosurgery” throughout because it is the common term in the scientific and medical literature and because it encompasses a broader range of behavioral-focused neurosurgeries than the more limited term “lobotomy.”

⁷⁸ MARK & ERVIN, *supra* note 76, at 1 (calling violence problem “solvable”; advocating psychosurgery and other brain interventions).

⁷⁹ Stephan L. Chorover, *Psychosurgery: a Neuropsychological Perspective*, 54 *B.U. L. REV.* 231, 232-33 (1974) [hereinafter “Chorover, *Psychosurgery*”] (quoting GOTTLEIB BURCKHARDT, UEBER RINGDENEXCISIONEN, ALS BEITRAG ZUR OPERATIVEN THERAPIE DER PSYCHOSEN, *ALLG. Z. PSYCHIAT.* (1891) (in which Burckhardt urges his colleagues to “tread the path of cortical extirpation.”)).

⁸⁰ The cerebral cortex is the outer layer of the brain, with all the characteristic convolutions and folds. It is believed to be an evolutionarily later development and the site of many of “higher” or distinctively human brain functions.

⁸¹ Chorover, *Psychosurgery*, 54 *B.U. L. REV.* at 232-33, *supra* note 79 (quoting GOTTLEIB BURCKHARDT, UEBER RINGDENEXCISIONEN, ALS BEITRAG ZUR OPERATIVEN THERAPIE DER PSYCHOSEN, *ALLG. Z. PSYCHIAT.* (1891)). This is the first instance of psychosurgery reported in any western medical journal. *Id.* It is beyond the scope of this

died and five remained at least as psychotic) and so it was not until nearly 50 years later that psychosurgery took off – following the chance encounter of a Portuguese politician and some apathetic monkeys.⁸²

In 1935, Antonio Egas Moniz, a retired Portuguese ambassador with training in neuroscience, attended the International Congress of Neurology in Boston.⁸³ There, two American researchers, John Fulton and Carlyle Jacobsen, presented their results on lesions in the frontal lobes and/or amygdalae of monkeys and chimpanzees: These primates ordinarily were hostile to researchers but, after bilateral lesions to their frontal lobes, were “strikingly indifferent to stimuli that previously had provided extreme agitation.”⁸⁴ They showed “drastic behavioral changes,” including deficits in learning and memory, but also were listless or “tame.”⁸⁵ Moniz asked the presenters if similar surgery could “tame” violent impulses in people.⁸⁶

Fulton and Jacobsen were “shocked” at Moniz’s suggestion, but Moniz put his idea into action immediately: On his return to Portugal, Moniz and a colleague performed 20 surgeries in a 10-week period on human subjects in which they destroyed portions of the patients’ frontal lobes.⁸⁷ Touting his successes, Moniz claimed that these people were

⁸² *Id.*

⁸³ *Id.* at 232 (quoting Moniz).

⁸⁴ *Id.*

⁸⁵ *Id.*

⁸⁶ *Id.*

⁸⁷ *Id.* Moniz’s original technique consisted of injecting alcohol and wax into portions of the brain, causing brain tissue to coagulate and die. Later, he refined his technique into what he termed the “leucotomy,” using a specially-designed cutting instrument, the leucotome, to remove portions of brain tissue. Later techniques were both more and less crude. Walter Freeman notoriously pioneered the “ice pick” lobotomy, a simple procedure in which an ice pick-like device was driven through the orbits of the skull and into the frontal lobes; given its simplicity, it was performed in a near-assembly line fashion. An innovation of greater sophistication was stereotactic neurosurgery, which, using three-dimensional maps of the brain and highly specialized surgical equipment, allowed for precise surgeries anywhere in the brain, including in its deeper structures like the amygdala. STANLEY FINGER, ORIGINS OF NEUROSCIENCE: A HISTORY OF EXPLORATIONS INTO BRAIN FUNCTION 292-4 (1994).

miraculously “cured,” that those “who had previously been violent ... became calm, tractable, and easier to manage.”⁸⁸ Lobotomy as a treatment for violence, cloaked in a heavy degree of (possibly self-deluding) misrepresentation about its safety and efficacy, was born.

Moniz’s purported successes with frontal lobe surgery (hence “lobe-otomy”) led him to receive the Nobel Prize in 1949.⁸⁹ And, it led to tens of thousands of psychosurgeries in the United States and around the world. In the United States alone, about 70,000 people were subjects of lobotomy between the 1940s and mid-1960s.⁹⁰

The fascination with brain-based causes of and potential “cures” for violence pervaded brain sciences in the mid-century. Animal studies, particularly with monkeys, rats, and one very famous bull seemed to point the way toward controlling man’s more animal nature. Proselytizers for the criminal law applications of “sedative psychosurgery,” as they called it, Vernon Mark and Frank Ervin, drew heavily on the same kind of monkey studies that first inspired Moniz. Mark and Ervin noted that “after both temporal lobes have been removed,” monkeys are “placid, can be easily handled, and do not respond aggressively even to attack ...”⁹¹ They also seem without anxiety, putting objects in their mouths “that ordinarily provoke fear, such as small snakes.”⁹² Showing even more dramatic examples of subduing primal violence, “[I]ocalized removal of the amygdala will tame a predatory and vicious lynx or a

⁹² *Id.*

wolverine.”⁹³ Analogizing people who have committed criminal violence to the “lynx or [] wolverine,” they note that, “[i]ndeed, neurosurgeons have surgically removed areas of the amygdala to treat assaultive behavior in patients[.]”⁹⁴

Around the same time, “an alternate form of psychosurgery”⁹⁵ – electrical stimulation of parts of the brain – also promised a solution to the “violence problem.” Throughout the 1950s and 1960s, the criminal law and scientific communities together explored electrical brain stimulation as a method to “effectively wipe out violence” in society.⁹⁶ The majority of this work consisted of electrical stimulation of parts of animals’ brains to evoke or suppress what the researchers characterized as violent behavior or inappropriate sexual behavior. In perhaps the most dramatic piece of theater a scientist ever staged, Dr. Jose Delgado of Yale University organized a bullfight – a special bullfight designed to show the triumph of neuroscience over animal aggression. Delgado arranged a “brave bull, a variety bred to respond with a raging charge when it sees any human being.”⁹⁷ Delgado implanted an electrode the caudate nucleus of the bull’s brain and, before a packed audience of scientists, media, and others, Delgado stopped the charging bull by activating the electrode – the power of science stopping animal aggression in its tracks.⁹⁸ Delgado’s work seemed to hold tremendous and direct promise

for law enforcement. Recruited by government agencies, Delgado worked for many years (although fruitlessly) on a brain-computer interface and on brain stimulation techniques to control human violence.⁹⁹

2. *Psychointervention and Criminal Law Initiatives*

While psychointervention, like phrenology and biological criminology, started out in asylums, it, too, soon made inroads into criminal law through its participation in the discourse on violence.¹⁰⁰ Indeed, if psychosurgery could fix the brain “dysfunction” causing violent conduct amongst the mentally ill, why stop at the asylum gates? Psychointervention might quell civil unrest (associated with the mid-century struggle for civil rights) and all kinds of other criminal violence.¹⁰¹ Particularly, psychosurgery might “treat” urban rioters, leaders of civil unrest (*i.e.*, those involved in the civil rights movement), and violent prisoners of all kinds.¹⁰² As the heralds of this transition of psychosurgery from a psychiatric treatment to an all-purpose social curative wrote: Psychointervention offers “a new and biologically oriented approach to the problem of human violence.”¹⁰³

Under the view of mind and behavior that animated psychointervention, violence can only arise from brain disorder – because with a “well-ordered brain,” a person “need never be out of control.”¹⁰⁴ If a person does “go out of control,” then there are only two possible reasons: “either the limbic system [which includes the amygdala] has become pathologically

⁹⁹ NPR Morning Edition, *Neuroscientists Gather in Washington to Discuss Cutting-Edge Research*, 2005 WLNR 25360638 (May 20, 2005) (noting that Delgado’s goal was to develop technologies such that governments could use brain stimulation to control people’s behavior).

(JAMA) 217, 217 (1967) (arguing that urban race riots were born not of rage at oppression or poverty but of physiological “dysfunction” in the rioters). *See also* MARK & ERVIN, *supra* note 76, at 1.

¹⁰² Chorover, *supra* note 79, B.U. L. Rev. at 245.

¹⁰³ MARK & ERVIN, *supra* note 76, at xi.

¹⁰⁴ MARK & ERVIN, *supra* note 76, at 32-33.

hyperactive” or “its neocortical [frontal lobe – executive function] inputs have become abnormal.”¹⁰⁵ In their landmark book *Violence and the Brain*, Professors Mark and Ervin of Harvard and MIT argued that such “brain dysfunction” causes “a low threshold for impulsive violence,” and that people convicted of a crime involving violence likely suffer from such brain disease.¹⁰⁶

Deriding views that crime rates reflect levels of policing, or socioeconomic or demographic factors, these researchers asserted that criminal violence is caused and explained exclusively by the perpetrators’ disordered neurobiology.¹⁰⁷ Thus, they recommended that people convicted of crimes of violence should have psychosurgery to remove their amygdalae.¹⁰⁸ In this, Mark and Ervin were emblematic of a broader movement in the biological control of violence, and particularly of proposals to perform psychosurgery or electrode implantation on prisoners.¹⁰⁹

While mass lobotomization of urban protesters and prisoners never did take place, a few experiments on prisoners tested out the idea.¹¹⁰ In 1968, under the auspices of the California Department of Corrections, several prisoners (including one minor) at the Vacaville State Penitentiary in Vacaville, California, underwent surgical implantation of electrodes for the purpose of destroying amygdalar tissue; the goal was to eradicate their desire and ability to

¹⁰⁵ *Id.*

¹⁰⁶ *Id.* at 2.

¹⁰⁷ *Id.* at xi (deriding theories that relate rates of violent crimes either to levels of policing or to social and economic factors).

¹⁰⁸ ELIOT VALENSTEIN, *BRAIN CONTROL* 255 (1974) (discussing the work of Mark and Ervin).

¹⁰⁹ For example, in 1970, the International Conference of Psychosurgeons entertained proposals to “initiate pilot programs for precise rehabilitation [through psychosurgery] of the prisoner-patient who is often young and intelligent, yet incapable of controlling various forms of violence.” E. VALENSTEIN, *BRAIN CONTROL* 255 (1974) (quoting remarks of M. Hunter Brown; internal quotation marks omitted).

¹¹⁰ Robert J. Trotter, *A Clockwork Orange in a California Prison*, *SCIENCE NEWS*, Mar. 11, 1972, at 174.

engage in violent behavior.¹¹¹ The experiment was carried out by a military surgeon from a nearby air force base, and Vacaville used its metalwork shop to craft a special device to hold the prisoners' heads in place for the procedure.¹¹²

The Vacaville experiment produced poor results: The one prisoner whose surgery the prison authorities deemed “successful,” and who was paroled, was re-arrested for robbery almost immediately after his release.¹¹³ Nevertheless, enthusiasm for solving criminal problems through psychointerventions went on unabated. In 1972, the Neuropsychiatric Institute of the University of California at Los Angeles proposed to develop a Center for the Study and Reduction of Violence, intended to identify violent predispositions and develop brain-based techniques for preventing and treating violent behavior.¹¹⁴ The Center was to be funded primarily by the federal Law Enforcement Assistance Administration (LEAA).¹¹⁵ In furtherance of its violence-prevention strategy, the LEAA also extensively funded research into brain implants and other brain intervention techniques.¹¹⁶

Ultimately, the once-heralded efforts to address criminal problems through psychosurgery and electrostimulation led lawmakers and neuroscientists alike to call to restrict the procedures, particularly on prisoners and children.¹¹⁷ Psychointervention is easy to dismiss as horrifying but irrelevant; the technology seems primitive, and there is little risk that similar

¹¹⁷ *See, e.g.*, S.J. Res. 86, 93d Cong., 1st Sess. (1973) (remarks by Sen. Beal, introducing a resolution calling for a two-year moratorium on psychosurgery during which the Secretary of Health, Education and Welfare would assess available data and make recommendations on the procedures); Chorover, *supra* note 79, B.U. L. Rev. at 247 (proposing creation of regulatory agencies at the state and federal level to recognize that psychosurgery is experimental; safeguard prisoners, children, and the mentally retarded; and develop a registry of all psychosurgery procedures to allow follow-up of patients who undergo psychosurgery).

technologies would be tested on prisoners and incompetents today, given the advent of rigorous Internal Review Boards for human experimentation and heightened ethical awareness.¹¹⁸

Yet, psychointervention has immediate lessons now. While we now know that the claims of psychointervention were inflated and we reject its abuses, its logic – like that of phrenology – is both elegant and fully consistent with prior movements in understanding violence entirely internally to the brain: Either violent people have disordered thoughts,¹¹⁹ produced by frontal lobes disorder; or they have abnormal fear and rage reactions, which arise from the amygdala.¹²⁰ The investigator then tries to solve what he or she has defined as the *brain's* violence problem through brain intervention – a seductively simple solution to a multifaceted and complex set of problems. In this, we see a version of the same argument currently advanced in reductionist approaches to neuroscience in criminal law – that dysfunction of the amygdala (or other parts of the brain regulating emotional processing), or of the frontal lobes, is the most prevalent and relevant cause of violent crime.

II. THE NEW CRIMINAL LAW AND NEUROSCIENCE OF VIOLENT CRIME

While many kinds of behaviors might be of legal and social interest,¹²¹ there “is a marked tendency” in neurobiological discussions of crime “to focus on violent behaviors.”¹²² Indeed, the “[p]rediction of violence,” as well as its control, is a central, shared interest of “science [and] the legal system” and is likely to remain a core area of collaboration between

these fields.¹²³ For this reason, there is “a massive (and growing) body of scientific literature on both the neuroanatomical and neurochemical bases” of violence.¹²⁴

The major criminal law prescriptions that are emerging from this work include challenges to retributive rationales for punishment and to capital punishment.¹²⁵ Extending the premises of this work further – centrally, that, because all human conduct emerges from a determined brain system and our sense of free will and choice are purely illusory – criminal law should proceed on consequentialist grounds only, with punishment being replaced by a system of medically-tailored rehabilitation.¹²⁶

While this is intended to be humane, it is worth keeping in mind Paul Robinson’s argument that “the harshness of the current system may be attributed in largest part to the move incapacitation and deterrence which disconnected criminal punishment from the constraint of just desert.”¹²⁷

A. Does Violent Crime Arises from PFC and Amygdalar Dysfunction?

Members of several fields who currently work on criminal violence assert that

¹²³ NEUROSCIENCE AND THE LAW, *supra* note 121, at 9 (in a section entitled “Predicting Violence”; no other section of the report expressly was dedicated to predicting any other type of behavior).

¹²⁴ Professor Snead has conducted an admirable literature review of the recent neuroimaging work on violence and aggression. See Snead, *supra* note 10, at 1298-99 (citing Antoine Bechara et al., *Insensitivity to Future Consequences Following Damage to Human Prefrontal Cortex*, 50 COGNITION 7, 8 (1994) (demonstrating connection between prefrontal lobe damage and impaired decision-making through neuropsychological testing); R. James R. Blair, Editorial, *Neurobiological Basis of Psychopathy*, 182 BRIT. J. PSYCHIATRY 5 (2003) (discussing neuroimaging studies finding association between amygdala dysfunction and psychopathy and noting probable impairment of orbitofrontal cortex in psychopathic individuals); R. James R. Blair, *Neurocognitive Models of Aggression, the Antisocial Personality Disorders, and Psychopathy*, 71 J. NEUROLOGY, NEUROSURGERY & PSYCHIATRY 727 (2001) (discussing neurocognitive models of aggression and relating them to explanations of antisocial personality disorder); Antonio R. Damasio, *A Neural Basis for Sociopathy*, 57 ARCHIVES GEN. PSYCHIATRY 128, 128- 29 (2000) (noting that the observed reduction in prefrontal white matter volume in psychopaths supports the view that sociopathy is “related to the malfunction of ... critical components in the prefrontal cortex”); Kent A. Kiehl et al., *Limbic Abnormalities in Affective Processing by Criminal Psychopaths as Revealed by Functional Magnetic Resonance Imaging*, 50 BIOL. PSYCHIATRY 677 (2001) (examining correlation between affective processing anomalies in criminal psychopaths and deficient input from limbic structures).

criminal violence arises as a result of dysregulation of the prefrontal cortex (“pfc”) and the amygdala – indeed, that these parts of the brain “play preeminent roles in [violent] behavior.”¹²⁸ So far, the “core findings” on violence and the brain are that the amygdala is involved in “fear and other negative emotions,” while the orbitofrontal cortex (a portion of the prefrontal cortex or pfc) contributes to “constraining impulsive outbursts[.]”¹²⁹ According to proponents of this view, a diverse body of research, including new neuroimaging and older animal studies, supports the notion that violent behavior initiates in the amygdala and that its expression is regulated by the pfc.¹³⁰

Impressive, even astounding, statistics support the claim that frontal lobe or pfc dysfunction is the major cause of all kinds of violent crime. Professor Richard Redding, citing Dr. Adrian Raine’s studies of incarcerated criminals, contends that “the prevalence rate [sic] of brain dysfunction ... [is] *ninety-four percent* among homicide offenders, [and] sixty-one percent

¹³⁰ See Snead, *supra* note 10, at 1294-95 and nn. 146, 148, & 150 (reviewing research on the relationship between amygdala and pfc function, and violent behavior). Some of the most significant work in this area includes: Richard L. Frierson & Ryan D. Finkenbine, *Psychiatric and Neurological Characteristics of Murder Defendants Referred for Pretrial Evaluation*, 49 J. FORENSIC SCI. 604, 605 (2004) (discussing studies observing frontal lobe dysfunction in murderers); M.C. Brower & B.H. Price, *Neuropsychiatry of Frontal Lobe Dysfunction in Violent and Criminal Behaviour: A Critical Review*, 71 J. NEUROLOGY NEUROSURGERY & PSYCHIATRY 720, 722-23 (2001) (surveying eighteen neuroimaging or neuropsychological studies touching on frontal lobe dysfunction and violent behavior); Adrian Raine et al., *Prefrontal Glucose Deficits in Murderers Lacking Psychosocial Deprivation*, 11 NEUROPSYCHIATRY NEUROPSYCHOLOGY & BEHAV. NEUROLOGY 1, 2 (1998) (examining whether “prefrontal dysfunction may specifically characterize violent offenders who lack psychosocial deficits”); Adrian Raine et al., *Reduced Prefrontal and Increased Subcortical Brain Functioning Assessed Using Positron Emission Tomography in Predatory and Affective Murderers*, 16 BEHAV. SCI. & L. 319, 321 (1998) (assessing “differences between affective and predatory murderers in cortical and subcortical brain functioning”); Adrian Raine et al., *Brain Abnormalities in Murderers Indicated by Positron Emission Tomography*, 42 BIOL. PSYCH. 495 (1997); Adrian Raine et al., *Selective Reductions in Prefrontal Glucose Metabolism in Murderers*, 36 BIOL. PSYCH. 365, 365-66, 370-71 (1994). In 2005, Jana L. Bufkin and Vickie R. Luttrell reviewed seventeen neuroimaging studies of aggressive, violent, and antisocial psychiatric patients, and concluded that prefrontal dysfunction is “consistently related to aggressive and/or violent behavior[.]” Jana L. Bufkin & Vickie R. Luttrell, *Neuroimaging Studies of Aggressive and Violent Behavior*, 6 TRAUMA, VIOLENCE, & ABUSE 176, 182 (2005).

among habitually aggressive adults[.]”¹³¹ By contrast, the claimed “prevalence rate [of brain dysfunction] in the general population is only *three percent*.”¹³²

While some more cautious legal scholars and neuroscience researchers note that the causal relationship between the degree of frontal lobe activity and any specific conduct is at best unestablished,¹³³ others leap forward: We are asked to believe that “neuroscience research ... provides *compelling explanatory evidence*” that frontal lobe dysfunction plays “a *causal role*” in most types of violent crime.¹³⁴ Following this view, understanding pfc and amygdalar dysfunction should provide the foundation for future “criminology, crime prevention efforts, and the functioning of the criminal justice system.”¹³⁵

B. Claims that Particular Crimes Arise from Specific Neural Patterns – A Biological Basis for Terrorism?

Related to the claims that dysfunction in two key brain regions are involved in violent crime, some scholars contend that particular types of neural activation patterns within these and related regions give rise to specific violent crimes. Future work, it is claimed, may establish the biological basis for all types of human violence, including “acts of ethnic cleansing,

¹³¹ Redding, *supra* note 3, at 57 (citing Nathaniel J. Pallone & James J. Hennessy, *Brain Dysfunction and Criminal Violence*, 35 SOCIETY 21, 21 (1998)). Note that Pallone and Hennessy used a particularly expansive definition of brain dysfunction.

¹³² *Id.* (emphasis added) (citing self, *Why It Is Essential to Teach About Mental Health Issues in Criminal Law (And a Primer on How to Do It)*, 14 WASH. U. J. L. & POL'Y 407, 408-10 (2004) (reviewing data on the prevalence of mental disorders among adults who come into contact with the criminal justice system)).

¹³³ See, e.g., Jedediah Purdy, *The Promise (And Limits) of Neuroeconomics*, 58 ALA. L. REV. 1, 3 (2006) (noting that, “[e]ven at its most sophisticated, brain imaging can only give us a map of correlations, which are physical events in the brain that correspond to the activity of the mind.”); *id.* at 14 (describing some neuroeconomics studies based on neuroimaging as “flirt[ing] with the emptiness of mere correlation.”).

¹³⁴ Redding, *supra* note 3, at 57-8 (emphasis added). See also, e.g., Adrian Raine et al., *Reduced Prefrontal and Increased Subcortical Brain Functioning Assessed Using Positron Emission Tomography in Predatory and Affective Murderers*, 16 BEHAV. SCI. & L. 319, 327-28 (1998); Adrian Raine et al., *Selective Reductions in Pre-Frontal Glucose Metabolism in Murderers*, 36 BIOLOGICAL PSYCHIATRY 365-66 (1994) (finding lower than average glucose metabolism in the lateral and medial prefrontal cortex of murderers who agreed to be tested; hypothesizing decreased activity in these brain regions may be predictive of one’s propensity to violence).

¹³⁵ Bufkin & Luttrell, *supra* note 130, at 176.

school shootings, bombings, hostage takings, [and] incidents of terrorism.”¹³⁶ It is suggested that there may be a unique “neural topography” for every crime ranging from “sadistic murder” to “political terroris[m].”¹³⁷ This understanding, in turn, “will contribute to its [violent crime’s] detection, control, and alleviation,” in part through predicting a person’s “level of dangerousness, and risk of recidivism[.]”¹³⁸ Additionally, with such an understanding of the causes (or at least markers) of particular crimes, lawmakers may be able to approach different types of criminal violence based on the (putatively) distinct neurobiology of each.¹³⁹

What is the basis for these claims? Research on the neurobiology of bombers themselves is extremely limited (and necessarily excludes subjects who might be of the greatest interest, successful suicide bombers).¹⁴⁰ The most comprehensive study of school shooters, issued in 2000 by the FBI, focused on behavioral warning signs; it did not investigate school shooters on the neurobiological level.¹⁴¹ To date, no studies have been conducted on neurobiology and terrorism¹⁴² or neurobiology and ethnic or political violence. Rather, these claims that specific crimes arise from specific brain dysfunction grow out of two important but indirect strands of research: decades of experiments on aggression in animals and a few recent human studies using functional magnetic resonance imaging (fMRI).¹⁴³

¹⁴³ For a synopsis of how brain images are made and interpreted, see, e.g., Laurence R. Tancredi & Jonathan D. Brodie, *The Brain and Behavior: Limitations on the Legal Use of Functional Magnetic Resonance Imaging*, 33 *AM.*

Animal models of aggression have provided the basis for research on human violence for about a century. In these studies, cats and rats display different patterns of brain activation depending on whether they were provoked to display “defensive rage” or “predatory aggression.”¹⁴⁴ (In ordinary English, “defensive rage” and “predatory aggression” in cats and rats translate roughly to “guarding territory from other cats or rats” and “preying on rats or mice.”) Violence researchers have extrapolated from these distinct patterns of aggression in animals that people, similarly, may have different neurological bases for what they call “hot” violence – crimes of sudden rage, like heat of passion crimes – and “cold” crimes of premeditation, like the proverbial cold-blooded killing.¹⁴⁵

In one recent article *Law, Responsibility, and the Brain*, the authors argue that a universal brain circuitry may underlie people’s “defensive” violent acts (like justified self-defense, as well as inappropriate violent responses to what a similarly situated reasonable person would not perceive as a threat) versus their “predatory” aggressive acts, like an act of revenge, a crime for financial gain, or other premeditated violent crimes.¹⁴⁶ Extrapolating further from the general categories of defensive and predatory aggression in cats and rats, the authors propose that distinct “neural topographies” may underlie specific types of crimes, ranging from “sadistic murder[.]” to “political terroris[m].”¹⁴⁷

J.L. & MED. 271, 272-76 (2007) (in a section entitled “Basics of Brain Imaging,” describing the mechanics of EEG, PET, and fMRI image production and interpretation). For a discussion of the “limitations and distortions” of fMRI, see *id.* at 278-80, noting that, among other difficulties, brain images can “vary significantly both between subjects and across sessions [with the same subject].” *Id.* at 280.

¹⁴⁴ *Id.*

¹⁴⁵ *Id.* For articles distinguishing between “hot” and “cold” crimes based on models of animal aggression, among many see, e.g., McEllistrem, *supra* note 136, at 14-15, and Leonard Berkowitz, *Is Something Missing? Some Observations Prompted by the Cognitive – Neoassociationist View of Anger and Aggression*, in AGGRESSIVE BEHAVIOR: CURRENT PERSPECTIVES 35, 35-7 (L. R. Huesmann ed., 1994).

¹⁴⁶ Mobbs et al., *supra* note 21, at 695 (this article represents a collaboration between specialists in neuroimaging and legal scholars).

¹⁴⁷ *Id.* at 695. It is unclear which of these crimes is supposed to be “hot” or “cold,” as high affect like rage, as well as premeditation, could be present in both.

On one level, these types of claims that distinct patterns of neural activation underlie different behaviors must be true: Insofar as there is a materialist basis for all human thought and action, then there likely are distinct neurobiological correlates for thinking of or engaging in any *X* versus any *Y* – say, liking or not liking a particular restaurant.¹⁴⁸ That proposition is likely to be uncontroversial, but also merely trivially true; it tells us nothing about *causation* – about the relationship between observed neural activation patterns, why those patterns are present, and how they relate to why people do the things they do.¹⁴⁹

The claim that a distinct “neural topography” might underlie “sadistic murder” or “political terroris[m]” is a much larger claim than the trivial truth claim above: This claim is not that brain activation patterns reflect and enable everything that people do (and that, on average, very similar patterns will underlie the same actions across neurotypical people). Instead, it is the claim that people engage in particular crimes *because of* specific, disordered neurobiology. At a minimum, under this view, the brain of a political terrorist would function differently from that of a sexual sadist; at the most, a person would become a terrorist or sexual sadist *because* he possessed a certain functional or structural neurobiological predisposition or defect. The authors expressly embrace this more radical claim, stating that while “[a]t first glance, such reasoning looks like phrenological folly,” nevertheless “studies strongly suggest that some kinds of criminal behavior are associated with dysfunction in particular regions of the brain.”¹⁵⁰

¹⁴⁸ See Elizabeth A. Phelps & Laura A. Thomas, *Race, Behavior, and the Brain: The Role of Neuroimaging in Understanding Complex Social Behaviors*, 24 *POLITICAL PSYCHOL.* 747, 754-55 (2003) (using the example of how experience with a restaurant would be encoded into one’s brain, but that that has little follow-on significance for).

¹⁴⁹ As Professors Phelps and Thomas, preeminent researchers on amygdalar function and behavior, note, “[a]lthough it often is exciting to demonstrate a neural basis for a given behavior, it should not be surprising to show that *any* behavior has a neural basis.” *Id.* at 754 (emphasis in original).

¹⁵⁰ Mobbs et al., *supra* note 21, at 695.

Only if the case is the latter is it meaningful to propose that lawmakers ought to approach crimes based on their distinct neurobiology – or that the criminal law finally could realize the Lombrosian dream of a biological criminology.¹⁵¹ Thus, this view of the neurobiology of violence, like its forbearers in other criminal law and neuroscience movements, posits that disordered brains are the most relevant site at which to understand the cause of violent crimes, and that many people who commit crimes of violence do so as a result of neurobiological dysfunction.

A recent and striking example of this type of imaging study is Professor Martin Walter's *Pedophilia Is Linked to Reduced Activation in Hypothalamus and Lateral Prefrontal Cortex During Visual Erotic Stimulation*.¹⁵² Walter's study is the first to use fMRI to compare the neurological responses of self-described pedophiles and self-described normal adults to erotic material featuring adults.¹⁵³ The researchers scanned the subjects' brains while the subjects looked at adult pornography. The fMRIs of pedophiles during the experiment showed reduced activation of the hypothalamus and prefrontal cortex "as compared to healthy individuals when they were viewing sexually arousing pictures of adults."¹⁵⁴ The study's authors suggest that pedophilia may arise from a defective neurological activation pattern (too little activity in the hypothalamus).¹⁵⁵

Brain imaging studies ultimately may contribute to understanding the origins and treatment of pedophilia. But an imaging study like this one has less explanatory power than it at

¹⁵¹ Note that Professor Redding, who suggests that biological criminology could be realized through this type of work (see Redding, *supra* note 3), is not one of the authors of this article, *Law, Violence, and the Brain*, *supra* note 21. The connection between these claims is that of the author of this Article.

¹⁵² Martin Walter et al., *Pedophilia Is Linked to Reduced Activation in Hypothalamus and Lateral Prefrontal Cortex During Visual Erotic Stimulation*, 62 BIOL. PSYCH. 698 (September 15, 2007).

¹⁵³ Walter, *supra* note 152, at 698.

¹⁵⁴ *Id.*

¹⁵⁵ *Id.*

first might seem, and little relevance for criminal law regimes aimed at pedophiles. Essentially, the researchers here correlated sexual arousal with activity in certain parts of the brain. This in itself is an interesting result that helps confirm the role of certain parts of the brain in arousal, but it does not reveal much, if anything, about the causes of pedophilia – or whether people who do or do not show such an activation pattern ever will abuse a child.

The results of this study would be expected by anyone who subscribes to a materialist view of consciousness – that is, that all our thoughts and emotions have some physical, detectable reality. Subjects who said they were attracted to adults showed activity in structures associated with arousal when they looked at erotic pictures of adults. The subjects who said in advance of the scanning that they were *not* attracted to adults did not show the same degree of activity in the those areas. This study thus neatly demonstrates that people show arousal when they see what turns them on and that they don't when they don't.¹⁵⁶ This fits the materialist model perfectly but does not support taking the leap to claims about the causes of pedophilia or even, apart from causation, whether such scans could be used to predict behavior in, *e.g.*, decisions about the release of an incarcerated pedophile.

Relatedly, this pedophilia study shows the degree to which scans may not reveal brain pathology *per se* but simply neural correlates of thoughts and behaviors that may be harmful, anti-social, or illegal. If another experiment were run in which normal adults failed to show brain arousal in response to *child* pornographic images, one might see the same lack of hypothalamic activation and concomitant absence of inhibitory pfc activity. Yet, we would not

¹⁵⁶ It is unclear why there would be any expectation that a group of subjects would have any response (neurological or otherwise) to an erotic category in which they have no interest. A group of shoe fetishists might show arousal in response to a patent leather stiletto but not to a handbag; handbags are the wrong fetish object. But one could not make the shoe fetishist a handbag fetishist just by juicing up the degree of activity in the hypothalamus.

define that as evidence of a brain dysfunction or speak of hypothalamic “deficits” in the subjects; for good reasons, we do not consider lack of sexual attraction to children to be pathological.

Defining activation or lack of activation in particular parts of the brain as “disorder” or “dysfunction” necessarily must start from a normative position about the thing that is being described. And so these definitions of biological dysfunction based on correlating brain activation patterns with legally proscribed conduct have an element of circularity. When we do this, we are reasoning from conclusions about abnormality and back-fitting them into scanner patterns. But we as yet have no basis on which to conclude that the activation pattern causally produces the proscribed thing or represents a medical pathology.

C. Tales of the Good Man Gone Bad – Brain Injury as Catalyst to Crime

Finally, scholars who contend that violence should be understood as a disease of localized brain dysfunction often point to one-off cases of outlandish injury or unusual disease to try to show that violence arises from disinhibition of the prefrontal cortex or dysfunction in the amygdala. In these case histories, damage to these areas causes previously law-abiding folk to transmogrify into impulsive, violent criminals – by extension, they support the implication that brain dysfunction is a major cause of criminal violence, making the individual brain the right level at which to explore and address such criminality.

The paradigmatic story of the relationship between frontal lobe dysfunction and violence, repeated in nearly all legal and popular science literature on the subject (and now to be repeated here), is that of Phineas Gage.¹⁵⁷ Phineas Gage was a law-abiding railway worker who,

¹⁵⁷ See UTTAL, *supra* note 57 at 165, n.4, calling the Gage story a “mainstay of pop psychology.” Among many sources repeating the Gage story, see, e.g., Peggy Sasso, *Implementing the Death Penalty: The Moral Implications of Recent Advances in Neuropsychology*, 9 CARDOZO L. REV. 765, 792-94 (2007) (devoting a section of the article to the Gage case; describing it as the seminal case on the relationship between damage to the prefrontal cortex and violent and/or sexual disinhibition of conduct); Joseph H. Baskin, Judith G. Edersheim, & Bruce H. Price, *Is a Picture Worth a Thousand Words? Neuroimaging in the Courtroom*, 33 AM. J.L. & MED. 239, 244 (2007) (describing Phineas Gage case to show relationship between orbitofrontal damage and violent behavior); Redding,

in 1848, suffered a bizarre industrial accident: An explosive charge meant to drive an iron tamping rod into the ground backfired – and drove the rod through Gage’s cheek-bone, behind his eye socket, and out the top of his head.¹⁵⁸ In addition to the direct trauma to his skull and brain, he also suffered major hemorrhaging and a brain abscess.¹⁵⁹ Amazingly, Gage’s injuries healed and he lived another thirteen years. Yet, he went through a marked change: He became ill-tempered and obstreperous.¹⁶⁰ For the rest of his life, Gage suffered a variety of deficits and frequently was in minor trouble with the law.¹⁶¹

The modern paradigmatic story linking violent criminality to brain disorder is the tragic story of Charles Whitman, an Eagle Scout, scholarship student at the University of Texas, and by all accounts loving husband and son, who murdered his wife, mother, and 14 students at the University of Texas on August 1, 1966.¹⁶² Whitman began to experience headaches and personality changes about a year before his attacks; he believed that he was suffering from a neurological problem and sought medical and law-enforcement help (including asking the police to arrest him earlier in the day that he committed his murders; the police were obliged to decline because Whitman had not yet committed any crime).¹⁶³ A post-mortem shortly after Whitman was shot by police showed a large tumor compressing Whitman’s amygdaloid nucleus.¹⁶⁴

A few recent cases follow a similar pattern: A socially respectable man – a

supra note 3, at 70-72 (discussing Gage case as exemplary of the relationship between orbitofrontal damage and violence); Raymond J. Dolan, *On the Neurology of Morals*, 2 NATURE NEUROSCIENCE 927, 927-28 (1999) (citing J.M. Harlow, *Passage of an Iron Rod Through the Head*, 39 BOSTON MED. & SURGICAL J. 389 (1848)) (discussing Gage’s treatment by his physician, Harlow).

¹⁶⁴ *Id.*

teacher, a stock broker – suffers a brain injury and morphs into a perpetrator of violence or sex crimes.¹⁶⁵ When the brain injury heals (or the tumor is removed), the man returns to his gentle and law-abiding ways.

While neuroscientists caution against reading too much into such stories,¹⁶⁶ less cautious criminal law and neuroscience scholarship makes a direct connection between Gage's accident and Whitman's tumor to violent crime in general. The work *Charles Whitman: The Amygdala and Mass Murder* typifies the genre.¹⁶⁷ The Gage and Whitman cases figured prominently in the recent symposium on neuroscience and the criminal law at Baylor University's center on Law, Brains, and Behavior. In the opening remarks of the conference, Dr. David Eagleman argued that the Whitman and Gage cases have important implications for criminal notions of culpability and provide the groundwork for understanding criminal violence as a medical problem arising from brain disorder.¹⁶⁸ Similarly, major criminology textbooks use Whitman's tumor as the starting point for a general explanation of violent crime as arising from brain dysfunction.¹⁶⁹

¹⁶⁵ See, e.g., Jeffrey M. Burns & Russell H. Swerdlow, *Right Orbitofrontal Tumor with Pedophilia Symptoms and Constructional Apraxia Signs*, 60 ARCHIVES OF NEUROLOGY 437, 437-38 (2003) (describing case of 40-year old man who engaged in uncharacteristic, unlawful sexual behavior incident to developing tumor in the orbitofrontal cortex, and whose behavior returned to normal after removal of tumor); Becky Sheaves, *The Freak Accident that Left My Son Obsessed with Sex*, DAILY MAIL, July 4, 2006, at 49 (describing the case of Andrew Laing, who, incident to a concussive injury to the frontal lobe, became physically and sexually aggressive).

¹⁶⁶ JAN VOLAVKA, THE NEUROBIOLOGY OF VIOLENCE 81-2 (2d ed., 2002) (describing factors making such cases difficult to extrapolate from, including: the multiple brain areas affected by the accident or lesion, the lack of control subjects, and, most significantly, sampling bias – people with brain injuries who become violent come to the attention of law enforcement and violence researchers, where as people with brain injuries who are not so affected do not).

¹⁶⁷ See Rhawn Joseph, *Charles Whitman: The Amygdala and Mass Murder*, article available at <http://brainmind.com/Case5.html> (last visited on August 12, 2008) (cited in GENARO F. VITO ET AL., CRIMINOLOGY 109 (2d ed. 2006)). Professor Joseph also treats the relationship between Whitman's case, the amygdalar complex, and aggression in NEUROPSYCHOLOGY, NEUROPSYCHIATRY, AND BEHAVIORAL NEUROLOGY 102-3 (1990), a standard introductory neuroscience text book.

¹⁶⁸ Dr. David Eagleman, Director, Baylor College of Medicine Initiative on Law, Brains, and Behavior, Introductory Remarks to Symposium on Law & Neuroscience, at Baylor College of Medicine (May 23, 2008).

¹⁶⁹ See, e.g., VITO ET AL., CRIMINOLOGY, *supra* note 167, at 95-96; LARRY J. SIEGEL, CRIMINOLOGY 142 (2005) (connecting Whitman's tumor to the "minimal brain dysfunction" explanation of violent criminality); MARK M.

The role that these case histories play in the literature is to show that criminal violence is a pathology – that it can be produced by brain trauma and alleviated by brain correction.¹⁷⁰ The view presented by this handful of brain trauma cases is that the most relevant level at which to understand the general phenomenon of criminal violence is internal to the individual – at the level of his or her neurobiology or neurochemistry – and, specifically, can be localized to the prefrontal cortex or amygdala. Finally, they present the claim that the violent person is fundamentally Other, essentially not-us, because he or she has a different (literally sick) brain. Thus, in these cases, we see all three of the major tenets of brain-behavior reductionism that historically have been manifest in past episodes of brain sciences in the criminal law.

III. METHODOLOGICAL ISSUES WITH CURRENT LAW & NEUROSCIENCE OF VIOLENCE

Bringing together anecdote and image, stories about the localization of violence in the brain are almost irresistible. They have the most current and sexy science apparently behind them, as well as decades of animal and human trauma research. Yet, there is “an enormous chasm” between what it is scientifically legitimate to say about “the localization problem” and what has “been concluded from well-intentioned, but inadequately reasoned research[.]”¹⁷¹ While it may not at first seem legitimate to lump the law and neuroscience of the new millennium with the science of lumps from the eighteen hundreds, this Part will show that infirmities continue to dog efforts to equate criminal violence with localized brain dysfunction – and that, for reasons inherent to the ways in which localization questions are posed, and the legal (not biological) content of definitions of criminal violence, likely will continue to do so.

LANIER & STUART HENRY, *ESSENTIAL CRIMINOLOGY* 101-2 (2004) (using Whitman story to introduce concept of “biogovernance” and prediction of violent crime).

DRAFT – NOT FOR QUOTATION; COMMENTS INVITED

To evaluate the claims that criminal violence is the result of brain dysfunction, this Part first will examine the current state of research on the localization of basic and higher brain processes. Starting with sensory-motor functions, it will show that, even for these relatively simple functions, the localization enterprise runs into problems. It then examines the state of research concerning the localizability of violence to the amygdala and prefrontal cortex, and some efforts to localize violence that have relied upon celebrated brain injury cases, like Phineas Gage and Charles Whitman.

As a final, formal barrier to localizing violence in the brain, “violence,” this Part will suggest, maybe be better understood as a legal term and a psychological construct than a biological thing. Legal institutions are essential to defining violence, as shown by the ways that legal definitions of what conduct constitutes violence change across place and time. Even outside of the legal domain, the concept of violence may have no specific biological reality; rather, it may be understood as a psychological construct – a term like “intelligence” or “attachment” that covers a range of mental activities and outward behaviors.

Each of these issues presenting a barrier to the straightforward localization of violence could be the subject of a book; while it is beyond this Article to address each of these issues comprehensively, this part sketches them to inform the legal reader of the active controversies surrounding the study of brain function and violence. Further, each of these questions goes back to the touchstone issues introduced in the beginning of this article: Whether the individual brain (or isolated parts of the brain) is the most relevant level at which to examine problems of criminal violence; whether it is possible to localize a heterogeneous set of behaviors called “violence” to dysfunction in parts of the brain; and whether people who engage in criminal violence may be biologically different from people who do not.

A. What We Know About Localization Generally

Theories of the localization of complex psychological phenomena, like violence, start from the premise that the brain is made up of specialized modules with distinct functions. Yet, the localization of even very basic brain functions is not as precise as generally is depicted in literature advocating for the localizable nature of violence. Even sensory and motor components of the brain are not neatly divided by function; this calls into question the soundness of hypothesizing that violence is discretely localized.

The brain is clearly not an undifferentiated mass: it is composed of various regions, which are visibly different both in their gross anatomy and cell structure (cytoarchitecture).¹⁷² Sensory and motor functions, in particular, occupy relatively specialized regions of the brain.¹⁷³ Some functional differences among these different regions are well-established: the brain stem regulates the most basic functions of the body's survival, such as breathing; the motor cortex, as the name implies, relates to motion and locomotion; specific parts of the brain also are involved in processing and interpreting sensory input such as visual images, smell, and sound. Some areas involved in uniquely human faculties, like speech, also have been identified: Broca's and Wernicke's regions, for example, play important (although not exclusive) roles in producing speech, and lesions in these areas can cause different kinds of aphasias.¹⁷⁴ Neuroscientists consider these sensory and motor functions to be the most easily localized to particular regions of the brain.

However, even for these "simple" brain functions, many parts of the brains are involved – and it is not yet known what their contributions are or how they relate to each other.

¹⁷² UTTAL, *supra* note 57, at 11.

¹⁷³ *Id.*

¹⁷⁴ MICHAEL F. BEAR ET AL., *NEUROSCIENCE: EXPLORING THE BRAIN* 621-25 (3d ed. 2006).

Indeed, it appears that no one part of the brain is sufficient, in isolation, to accomplish any function of a living being.¹⁷⁵ Further, individual variation in brain structure is enormous – particularly among human beings – meaning that the locations in the brain that are involved in one process in one person will not be identical in another person.

Three beautiful and careful examples of neuroscience research on sensory and motor systems – specifically, the auditory, visual, and motor systems – illustrate the difficulties with localizing even these more basic brain functions.

Processing sound, a basic sensory operation, involves several, known regions of the brain. Yet, putting those components together into “hearing” is not localized to any one part of the brain or even to one general region. If a person is surprised with the sound of a whistle, fMRI imaging shows that twenty-four distinct areas in the brain become active.¹⁷⁶ Prior to imaging studies, neuroscientists would have assumed that many of these areas were not implicated in sound processing at all.¹⁷⁷ Some of the regions may be associated with surprise, sound-identification, and memory (What does a whistle mean to me?). Thus, a brain scan showing these twenty-four areas lit up would not translate directly to ... any specific conclusion. No conclusion can be drawn from such a scan about the necessity or sufficiency of any of these regions to processing sound generally or to the identification of a whistle specifically. Nor would it be possible to read backward from the scan either that the person heard a whistle or what a whistle noise means to him or her.

That multiple sites are activated in response to a simple auditory task suggests that scientists and legal scholars “cannot assume that a brain site is necessary for a psychological

¹⁷⁵ KAGAN, *supra* note 89, at 214.

¹⁷⁶ *Id.*

¹⁷⁷ *Id.*

process just because it was active during the process.”¹⁷⁸ This issue with sound processing represents the more general problem of “necessary but not sufficient.” For although “it is clearly true that we can say of particular brain regions that they are *necessary* for given behaviors (or their expression),” decades of experiments show that “there is no region of the human brain [including the amygdala or pfc] of which we can say that it is *sufficient* for such functions.”¹⁷⁹

The visual system presents greater complexity and demonstrates a distinct problem. Neuroscientists working on how the brain processes visual stimuli to create “seeing” have made tremendous progress. Going back to the early 1990s, neuroscientists have been able to discern and describe a series of feedback and feedforward systems between brain “modules” that contribute to the overall gestalt of “seeing.”¹⁸⁰ These “modules” have been organized by researchers into a hierarchical model that purports to show the contributions that each one makes to seeing.¹⁸¹ And yet even here, there may not be the degree of functional localization previously assumed.

Because of the “basic properties of interconnected networks,” it appears likely that “complex systems like [the visual system] cannot be organized into a unique hierarchical organizational chart.”¹⁸² According to systems biologists, who work on the mathematics of complex, non-linear systems, there is “an *in principle* barrier to the specification of a network hierarchy” like the brain processes that interrelate to create “seeing,” “*no matter how many experiments may be carried out.*”¹⁸³ While scans of auditory activity raise the necessary/sufficient/incidental problem, the current understanding of the visual system raises the

¹⁸³ *Id.*

issue that, in a complex networked system, it may be *formally* (that is, mathematically) impossible to determine the independent contributions of different components.

Work in the motor system highlights a third challenge to localization – individuality; the unique make-up of every person. Cutting-edge experiments in neuro-robotics (brain-robot interfaces) demonstrate that brains are unique in important ways even as to simple motor functions, like moving one’s arm. MacArthur-prize winning neuroroboticist, Yoky Matsuoda, is showing that the motor neurons of every person’s brain are organized with important differences that defy precise localization.

Professor Matsuoda’s work focuses on designing cybernetic limbs an amputee can control through thinking about moving the missing limb.¹⁸⁴ To do this, she introduces electrodes into the specific neurons in the subject’s brain responsible for activating arm movement.¹⁸⁵ This would sound as if it supports the localization notion, at least for motor functions. And yet, this is not the case. She explains:

A person’s history determines which neurons control the arm. Even in identical twins, the same neuron in one person could activate the arm, but in the other twin, it could activate the leg. It depends on what the person has touched, seen, done, at critical points in his or her development.¹⁸⁶

For this reason, it is not possible to identify a general “arm movement location.”¹⁸⁷ This is not surprising, because “if our brains were not individual, we could not be individuals.”¹⁸⁸

These problems of localizing sensory-motor functions proliferate as we move to the localization of cognitive functions. Sensory and motor aspects of brain function are anchored to dimensions of time, space, quality (*e.g.*, hot, cold, wet), and intensity; the “further we move

¹⁸⁴ Dr. Yoky Matsuoda, personal communication, February 16, 2007 (Santa Barbara, Ca.).

¹⁸⁵ *Id.*

¹⁸⁶ *Id.*

¹⁸⁷ *Id.*

¹⁸⁸ *Id.*

from the sensory aspects of cognition ... the more difficult it becomes to find particular brain regions exclusively and uniquely associated with a particular cognitive process.”¹⁸⁹

Neuroscientists active in localization research concerning higher cognitive functions confront the following problems:

- Cognitive functions activate broadly distributed regions of the brain;
- Brain regions are complexly interconnected;
- Lesion experiments [or accidents] can confirm the involvement but cannot confirm sufficiency of any region to the function under study; and
- Human neuropsychological and experimental data are idiosyncratic.¹⁹⁰

These are but a few of the issues that “shadow[]” efforts to localize complex cognitive functions “with serious and complex conceptual troubles.”¹⁹¹

B. The Limits of Localizing Violence to the PFC and Amygdala

1. Challenges Posed By Claims About PFC and Amygdalar Function

Legal scholarship advocating for a primarily brain-based understanding of violence hangs substantially on claims about the pfc and the amygdala. Yet, different neuroscientists have come to widely disparate conclusions about the functions of the pfc and the amygdala, implicating them in diverse mental processes unrelated to violence. This lack of consensus should give legal scholars pause before adopting a view about the localization of violence to these parts of the brain.

Looking at research on the pfc first: The prefrontal cortex is without doubt one of the most intricate and sophisticated parts of the brain. Indeed, there is hardly a higher-level cognitive process that one or another researchers has not localized to the frontal lobes. These include, among others:

- general intelligence¹⁹²

¹⁸⁹ UTTAL, *supra* note 57, at 25.

¹⁹⁰ This list is reproduced from Uttal, *supra* note 57, at 153. Uttal discusses each of these issues in depth, at 153-66.

¹⁹¹ *Id.* at 26.

- problem solving¹⁹³
- executive control¹⁹⁴
- attention¹⁹⁵
- decision-making¹⁹⁶
- semantic memory¹⁹⁷
- perceptual analysis¹⁹⁸
- self-awareness; sense of self¹⁹⁹
- “the creation and maintenance of explicit relational representations that guide thought and action”²⁰⁰
- “free won’t”²⁰¹

This list of functions, which is itself extremely broad, only shows the tip of the proverbial iceberg: A literature review by several neuroscientists of the functions imputed to the pfc produced a seven-page list of different attributions.²⁰²

The pfc may be involved in all of these activities, and others yet to be determined.

If so, what would decreased activation of a person’s pfc in a particular situation tell us? The answer is: Nothing unambiguously related to the disinhibition of violent conduct. Since activity

²⁰⁰ N. Robin & Keith J. Holyoak, *Relational Complexity and the Functions of the Prefrontal Cortex*, in *id.* at 987, 996.

²⁰¹ “Free won’t” is what Michael Gazzaniga describes as the ability to stifle inappropriate thoughts, speech, or action. Even if the pfc is the site of “free won’t,” it is unclear how or where the brain determines what is or is not appropriate under the circumstances. Gazzaniga’s localization of “free won’t” to the pfc is a wonderful companion to, among others, Renee Descartes’ localization of free will to the pineal gland. See, e.g., PETER A. SCHOOLS, *DESCARTES AND THE ENLIGHTENMENT* 169 (1989). In Gazzaniga’s schema, however, people are without such a construct as “free will”; rather, our thoughts and actions are totally determined *ex ante* by the structure of our brains. GAZZANIGA, *ETHICAL BRAIN*, *supra* note 11, at 98.

²⁰² UTTAL, *supra* note 57, at 23-24 (describing and citing J. Grafman, A. Partiot, and C. Hollnagel, *Fables of the Prefrontal Cortex*, 18 *BEHAV. & BRAIN SCI.* 349 (1995)).

in the pfc could be related to some, all, or none of the functions above, pfc activity cannot translate directly into impulse control; lower activation does not mean that a person will act on a violent urge and higher activation does not mean that a person will not act on a violent urge.

Similarly, numerous respected brain researchers question the localization of fear to the amygdala,²⁰³ and the leap from fearfulness to violence, because “the amygdala can be activated by many events that have no relation to fear.”²⁰⁴ Pictures of food, the face of an old friend, and couples hugging or kissing, among other images, provoke amygdalar activity as long as the images are unexpected.²⁰⁵ If a subject thinks he is in an experiment to identify playing cards, and the researcher “shows you a picture of scrambled eggs, your amygdala will light up.”²⁰⁶ This is not because the subject is afraid of or angry about scrambled eggs, but just because the picture is unexpected.²⁰⁷ This group of researchers believes that “the amygdala gets involved when there’s news.”²⁰⁸

Other prominent contemporary researchers, like Elizabeth Phelps, depict the amygdala’s role as mediating between emotion and cognition,²⁰⁹ and providing a basis for

²⁰³ These include, *e.g.*, Eliot Valenstein, William Uttal, Jerome Kagan, and Stephan Chorover. *See* KAGAN, *supra* note 89, at 92 (describing various types of stimuli that lead to activation of the amygdala).

²⁰⁴ KAGAN, *supra* note 89, at 92.

²⁰⁵ *Id.*

²⁰⁶ Interview with Stephan L. Chorover, Department of Brain & Cognitive Sciences, Massachusetts Institute of Technology, Jan. 29, 2008 [“Chorover, Interview”].

²⁰⁷ *Id.* *See also* KAGAN, *supra* note 89, at 86-87 (“The brain’s first question to every intrusion is: Was this event expected or unexpected? Less than two-tenths of a second later, it evaluates the specific meaning of the event and may generate an emotional response.”)

²⁰⁸ Chorover, Interview, *supra* note 206. *See also* KAGAN, *supra* note 89, at 86 (noting that an equal degree of amygdalar activity occurs in response to images of nudes as to angry or fear-provoking images). There could be a relationship between how sensitive a person is to “news” and how fearful he or she is; the two might be related at the level of how easily startled the person might be. A person who is easily startled *might* be excessively fearful, and thus *might* be prone to a greater degree of reactive violence – but that relationship is, on current information, purely hypothetical.

²⁰⁹ Elizabeth A. Phelps, *The Human Amygdala and Awareness: Interactions Between Emotion and Cognition*, in COGNITIVE NEUROSCIENCES, *supra* note 192, at 1005.

interpreting social information.²¹⁰ Still another view is that the amygdala plays a role in visual memory.²¹¹

The functions of the amygdala could be (and are) the subject of numerous books and scholarly articles. The purpose of this brief discussion is to show the unreliability of claims that draw a linear relationship between amygdalar activity and criminal violence.

2. *Challenges in Correlating Scan Data and Subjective Experience*

A final challenge to the relationship between amygdalar or pfc activation and propensity to violence is that substantial discrepancies can exist between activation patterns in an fMRI and what people subjectively self-report about their emotional state. This raises the important question of what to believe – what a scan indicates is going on in a person’s head or what the person claims to experience.

Interestingly, some studies find “little or no relation between verbal reports of the intensity of anxiety or fear to pictures of angry or fearful facial expressions and the amount of activity in the amygdala.”²¹² The same is true when we move from fear or violence to sex: Measures of women’s physiological response to pornography and their self-reported experience of arousal (or, more typically, lack thereof) correlate poorly.²¹³

The divergence between brain scan data and reported subjective experience raises an important question about detecting and regulating criminal violence. We might credit a

²¹³ *See, e.g.*, A.H. Rellini, et al., *The Relationship between Women’s Subjective and Physiological Sexual Arousal*, 42 PSYCHOPHYSIOLOGY 116 (2005).

woman’s self-report that she does not feel turned on by pornography even if biological indicators show activity consistent with arousal – whether because we believe she has no incentive to deceive or because it accords with cultural expectations. But what about differences in self-reporting versus scanning in an offender who is up for parole review? Would we credit his claims not to have violent impulses, even though a brain scan indicates reduced activation in the pfc or greater activation in the limbic system relative to standard ranges?

This is a question with serious implications for some of the proposed uses of fMRI data in criminal adjudications: How, generally, could we assess a discrepancy between an fMRI and self-reported mental state, in light of the fact that there can be authentic discrepancies between feelings and scans, and that both the subject and the interpreter of the might be influenced by incentives and biases? Given the tendency to credit as objective any data that appears in the form of a picture and that is proffered by socially-respected sources,²¹⁴ we well might privilege scans over self-reports – and be mistaken in doing so.

3. *Challenges of extrapolating from animal models*

While researchers have implicated the pfc and amygdala in a huge range of functions distinct from violence, the researchers who advocate for a close violence-amygdala/pfc connection often show empirical support for their claims through animal studies. These animal studies provide what appear to be direct and compelling evidence of the role of the amygdala, in particular, in causing violence. The raging bull and the wild monkeys reduced to tameness through interference with their limbic systems – did they not show an amazing absence of aggression?

²¹⁴ See generally Jennifer L. Mnookin, *Fingerprint Evidence in an Age of DNA Profiling*, 67 BROOK. L. REV. 13 (2001) (discussing judicial and public acceptance of fingerprinting); Jennifer L. Mnookin, *Scripting Expertise: The History of Handwriting Identification Evidence and the Judicial Construction of Reliability*, 87 VA. L. REV. 1723 (2001) (discussing judicial reception of handwriting identification as a form of scientific evidence).

In fact not. After initial reports that destruction of the amygdala could render “wild” and “aggressive” animals “tame,” further experiments showed that the animals likely were suffering from a disruption to their visual memory: So, it was not the case that the animals were without fear, but that they failed to recognize what they were looking at.²¹⁵ Thus, their normal fearful or aggressive reaction disappeared because of interference with contextual thinking, not because the amygdala is the storehouse of fearful or aggressive impulses. Indeed, these animals still acted with equal “aggressiveness” to threatening physical stimuli, like being prodded.²¹⁶ Their “violent” responses to unpleasant touch but apparent tameness toward everything else makes perfect sense as an unintended consequence of disruption to visual memory: If you do not know what a snake is, you might pick it up and be curious about it. But if it bit you, you’d still throw it down – a “violent” reaction.

Beyond problems with experimental design that could permit conflation of loss of visual recognition or partial paralysis with loss of aggression, the use of animal models in studying human violence, although productive and important, presents certain problems. As discussed in Section III.B, most research on the relationship between the amygdala and animal aggression has been conducted on cats and rats. These experimental animals are cheap, easily available, and share some important basic biology with people. While researchers frequently extrapolate from animal models to human models, brain and behavior are areas where particular care must be taken with “transphyetic extrapolation.”²¹⁷ It is worth remarking on two features cats and rats share, and that humans do not: First, cats and rats are territorial. Second, and also unlike humans, they normally attack mice. Cats and rats have evolved brain systems that enable

²¹⁵ Chorover, *Violence: A Localizable Problem?*, *supra* note 211, at 263.

²¹⁶ *Id.*

²¹⁷ See, e.g., T.C. Schneirla *Behavioral Development and Comparative Psychology*, 41 *QUARTERLY REV. OF BIOL.* 283, 285 (1966).

them be territorial and to attack certain prey; the amygdala may play some role in these stereotypical cat and rat behaviors that it does not play in the human being.²¹⁸

Evolution is conservative – that is, it does not proliferate new structures for new purposes but generally recruits existing structures to new purposes.²¹⁹ In mammalian species, much brain anatomy is the same and yet the functions facilitated by the same brain structures differ between different genres. This has been shown to be true of the amygdala. Lesions to the amygdala disrupt social communication in some primates, but not in humans.²²⁰ Conversely, lesions near certain language processing areas cause people to have serious social deficits, but, in other primates, “social communication ... is unaffected.”²²¹ If such differences in amygdalar function exist between people and our closest primate relatives, it is reasonable to ask whether the differences might not be even greater between people and rats or cats.

Extrapolating freely from these experiments, though, in which cats and rats are quicker to attack an intruder if their amygdalae are stimulated and slower or indifferent if their amygdalae are excised, researchers claim that the amygdala plays an important role in human “defensive rage.” They hypothesize that a person who is often violent – who, for example, commits frequent acts of road rage or domestic violence – has an over-active amygdala that interprets innocuous stimuli as provocative insults. This kind of excessively violent reaction, hypothesized to spring from amygdalar overactivation, is then (rather circularly) claimed to show that violence is a type of brain pathology.

²¹⁸ For a classic statement of this principle, see Steven J. Gould & Richard C. Lewontin, *The Spandrels of San Marco and the Panglossian Paradigm: A Critique of the Adaptationist Programme*, 205 PROC. ROYAL SOC. OF LON., SERIES B, BIOL. SCI., 581, 594 (1979) (discussing phyletic and developmental constraints on evolutionary innovation).

²¹⁹ *Id.*

²²⁰ STEVEN E. HYMAN, *THE SCIENCE OF MENTAL HEALTH* 126-27 (2001).

²²¹ *Id.* at 123.

The problems that can flow from very ambitious extrapolations from animal models are evident in the connection of normal aggression in cats with terrorism by people.²²² From the literature on “defensive rage” and “predatory aggression” in cats and rats, some researchers have asserted (as noted in Part II.B) that unique “neural topographies” might underlie specific human crimes – including whether a person becomes a “political terrorist.”²²³ Even holding aside the problems of cross-species extrapolation, the related problem of meaning is obvious: Terrorism is an inherently political concept that has a plethora of definitions and no independent biological reality.²²⁴ There simply is no way to extrapolate from activation patterns in animal brains to conclusions about (putative) biological bases of human terrorism – much less legal prescriptions for intervention in the same.

4. *Issues with extrapolation from human brain injury cases*

If claims about the localization of violence based on animal experiments are suspect, what about evidence directly from human beings? Accidental brain injuries and brain

²²² See discussion, *supra*, at the text accompanying notes 146 - 139.

²²³ Mobbs et al., *supra* note 21, at 695.

²²⁴ The Second Circuit (among other bodies) has concluded that there is no generally-accepted definition of “terrorism”:

We regrettably are no closer ... to an international consensus on the definition of terrorism or even its proscription; the mere existence of the phrase “state-sponsored terrorism” proves the absence of agreement on basic terms among a large number of States that terrorism violates public international law. Moreover, there continues to be strenuous disagreement among States about what actions do or do not constitute terrorism, nor have we shaken ourselves free of the cliché that “one man's terrorist is another man's freedom fighter.”

United States v. Yousef, 327 F.3d 56, 106-07 (2d Cir. 2003). See also *id.* at notes 41 & 42.

International treaties and domestic laws offer a plethora of conflicting and controversial definitions of “terrorism.” For a small sampling, see, e.g., Declaration on Principles of International Law Concerning Friendly Relations Among Co-operating States in Accordance with the Charter of the United Nations, Oct. 24, 1970, G.A. Res. 2625, 25 U.N. GAOR Supp. (No. 28) at 21, U.N. Doc. A/8028 (1971), reprinted in 9 I.L.M. 1292 (1970); European Convention on the Suppression of Terrorism, Nov. 10, 1976, Europ. T.S. No. 90; Arab Convention on the Suppression of Terrorism (Cairo, Apr. 22, 1998), reprinted in International Instruments Related to the Prevention and Suppression of International Terrorism, 152-73 (United Nations 2001); 18 U.S.C. § 2331 (defining terrorism by motive); 6 U.S.C. § 444(2)(B) (defining terrorism by its effect on United States interests); 8 U.S.C. § 1182(a)(3)(B)(ii) (excluding aliens based on participation in “terrorist activity” involving, *inter alia*, attacks on third parties to influence the policy of any government). Scholars have their own definitions as well. See, e.g., ALEX P. SCHMID & ALBERT J. JONGMAN, POLITICAL TERRORISM 1-2 (1988) (“Terrorism is a method of combat in which ... symbolic victims serve as an instrumental target of violence.”).

diseases have produced a host of illuminating scientific curiosities that sometimes have led to medical breakthroughs.²²⁵ But the Gage and Whitman stories are canards that contribute very little to understanding criminal violence. Although brain injuries can be catastrophic, there is no reliable relationship between pfc damage and violent or impulsive behavior. While in some cases “relatively large volumes of brain can be ‘disconnected’ without much obvious consequence,” in other cases extremely small traumas of a few millimeters can “have devastating effects.”²²⁶ Brain injury continues to puzzle, and throws more caution than light on simplistic localization arguments about the functioning of intact brains.²²⁷

For these reasons, it is “surprising[.]” that “a few scientists” have started to use pfc activity levels “as a referent for moral feeling or judgment.”²²⁸ While it is true that certain “[p]sychopaths who are shown an aggressive picture ... display less activation” in the pfc than neurotypical people, the reverse is not true: “Most adults with damage to, or compromise of, the orbitofrontal prefrontal cortex never commit a serious crime, whereas most who lie, cheat, and steal have perfectly intact brains.”²²⁹ This is not to say that a brain trauma or disease could not produce dramatic personality changes; it could. The questions of how the brain re-routes around and compensates for injuries, and how it continues to change throughout a person’s life, form a

²²⁵ KENNETH M. HEILMAN & EDWARD VALENSTEIN, *CLINICAL NEUROPSYCHOLOGY* 15 (2003) (describing effect of lesion in Broca’s area to speech; describing relationship between other lesions and distinctive speech problems). Brain disease is more likely to lead to greater understanding of the normal function of the affected portion of the brain where the disease afflicts enough people, in a sufficiently consistent way, that it is possible to generalize about the impact of damage of a particular kind to a particular part of the brain. See, e.g., Reiner Sprengelmeyer et al., *Recognition of Facial Expressions: Selective Impairment of Specific Emotions in Huntington’s Disease*, 14 *COGNITIVE NEUROPSYCHOL.* 839, 839-40 (1997) (describing deficits in Huntington’s patients with lesions to same portion of brain); JM Gray et al., *Impaired Recognition of Disgust in Huntington’s Disease Gene Carriers*, 120 *BRAIN* 2029 (1997); R. Adolphs et al., *Impaired Recognition of Emotion in Facial Expressions Following Bilateral Damage to the Human Amygdala*, 372 *NATURE* 669 (1994).

²²⁶ LEWONTIN ET AL., *NOT IN OUR GENES*, *supra* note 179, at 190.

²²⁷ Chorover, *Violence: A Localizable Problem?*, *supra* note 215, at 263 (“Brain lesions, whether the results of operations or accidents in humans, or in controlled animal experiments, have continued to produce puzzles and paradoxes.”).

²²⁸ KAGAN, *supra* note 89, at 130.

²²⁹ *Id.*

whole field of inquiry in their own right. The limited point here is just that isolated stories like those of Gage and Whitman may have less to say than is claimed about them or than at first it may appear.

C. Violence as a Legal Term and Psychological Construct

In order for violence to be localizable to activity in specific parts of the brain, or to particular brain dysfunctions, it must designate a coherent or homogenous thing. “Violence,” however, designates a huge range of individual, group, and even national behavior.²³⁰ What the law recognizes as violence changes greatly over time and place. Violence takes its meaning from the law, background social norms, and the particular context in which the violent acts take place.²³¹

Two relatively recent changes in the criminal law illustrate the legally-contingent nature of what a society calls “violence”: the creation of the category of domestic violence and the proscription of one kind of sexual violence through the elimination of the marital rape exception. Prior to the latter quarter of the twentieth century, victims of abuse by intimates might have identified their abusers’ conduct as violent – but legal culture did not. Until Pennsylvania passed its landmark Protection from Abuse Act in 1977, domestic violence was largely unrecognized and not separately legally actionable.²³² With the stroke of a legislator’s pen, acts that previously did not rate the designation “criminal violence” suddenly became legally defined as such.

The marital rape exception tells the same story as to sexual violence in the home. Until relatively recently, state courts across the United States presumed that a husband had a

²³¹ ELIZABETH STANKO, THE MEANINGS OF VIOLENCE 2-3 (2003).

²³² EVE S. BUZAWA & CARL G. BUZAWA, DOMESTIC VIOLENCE: THE CRIMINAL JUSTICE RESPONSE 109 (2003) (describing history of enactment of anti-domestic violence legislation in the United States).

right to sex at any time within marriage, regardless of the wife’s actual consent.²³³ After much legal and social contestation, this aspect of what previously was a conjugal right became redefined as marital rape; a husband who was exercising his legally-sanctioned rights one day became the perpetrator of criminal sexual violence the next. This was a change in the law, not a change in perpetrators’ brains.²³⁴ Today, in much of Asia and the Middle East, the marital rape exception endures;²³⁵ thus, the same conduct that is “criminal violence” in one culture is not considered “violence” at all under the laws and mores of another. This small example illustrates that what counts as violence depends substantially on who gets to define it.

As discussed above, social unrest incident to the struggle for civil rights was a major impetus in the 1960s for calls for wide-spread lobotomy. Drs. Sweet, Mark, and Ervin explicitly linked their localization theory of violence to neurobiological differences in race rioters: Because some African-Americans rioted and others did not, they reasoned, the only explanation for this distinction must lie outside the slum conditions in which both rioters and non-rioters lived. Rather, there must be a “brain proneness to violence” amongst those who rioted.²³⁶

Surely, the acts of rioters count as “violence” under any customary definition. However, Drs. Mark and Ervin notably failed to consider that mass injustices perpetrated by whites against African-Americans also might constitute “violence.” No contemporary proposals

²³³ Rebecca M. Ryan, *The Sex Right: A Legal History of the Marital Rape Exception*, 20 LAW & SOC. INQUIRY 941 (1995) (providing a history of the challenges to, and defeat of, marital rape exceptions in the United States). For a comprehensive treatment of this subject, see DIANA E. H. RUSSELL, *RAPE IN MARRIAGE* (1990).

²³⁴ Except to the extent that internalized norms might alter brain structure or function, on a materialist view of thought. So, a change in norms might cause a change in brain biology – but that is not the causal direction we find in arguments about the neurobiology of violence.

²³⁵ AIHWA ONG, *NEOLIBERALISM AS EXCEPTION: MUTATIONS IN CITIZENSHIP AND SOVEREIGNTY* 49-50 (2006) (discussing the marital rape exception under Islamic law; noting that many Asian legal scholars view the marital rape exception as an unacceptable “Western import”; the views of Asian and Muslim women on this subject, however, are not reported).

²³⁶ Mark et al., *supra* note 101, at 217.

were advanced to, for example, conduct neurobiological studies of white supremacist gangs or enthusiastic Southern sheriffs to determine the brain disorders underlying *their* predispositions to violence. Nor were any proposals for “therapeutic lobotomy” or “sedative neurosurgery” advanced for dealing with the then-widespread problem of white violence. Thus, while the laws at the time proscribed both rioting and the acts of individual violence by whites against blacks, only the conduct of one group appeared problematic; thus we see that *who* is described as violent, as well as what is described as violence, also depends on who is making the judgments.

Moving outside of legal definitions, violence may be understood better as a psychological construct than as a biological fact.²³⁷ Psychological constructs describe general features observed across people, like “intelligence” or “memory,”²³⁸ that are united by functional similarities, or family resemblances, more than by a common biology.²³⁹ Psychologists do not consider these to be real “things” that can be measured in the same way as, *e.g.*, height, although they can be measured functionally.²⁴⁰ Psychological constructs may be valuable, and may map well onto behavior; yet, it is well recognized that they may have no relationship to a particular underlying biology at all.²⁴¹

²³⁷ A psychological construct “is a theoretical idea developed to explain and to organize some aspects of existing knowledge.... [It is] a work of informed scientific imagination ... understood from its network of relationships.” American Psychological Association, Standards for Educational and Psychological Tests 29-30 (1974).

²³⁸ James R. P. Ogloff & Kevin S. Douglas, *Psychological Assessment in Forensic Settings*, 346, 355, in HANDBOOK OF PSYCHOLOGY, VOL. 10 (John R. Graham & Jack A. Naglieri eds., 2003).

²³⁹ The relationship between psychological constructs, on the one hand, and physical reality on the other, goes to the heart of profound issues in fields ranging from cognitive psychology and neuroscience to linguistics and philosophy. See, for example, HILARY PUTNAM, REPRESENTATION AND REALITY 7 (1988) (challenging Noam Chomsky’s notion of mental modules). Putnam fires a shot over the bow at the notion that there is a correspondence between either mental states or psychological representations, and physical reality, stating that there is a “general tendency in the history of thought ... to think of concepts as scientifically describable (‘psychologically real’) entities in the mind or brain. And it is this entire tendency that, I shall argue, is misguided.” *Id.*

²⁴⁰ STEVEN J. OSTERLIND, CONSTRUCTING TEST ITEMS: MULTIPLE-CHOICE, CONSTRUCTED RESPONSE, PERFORMANCE, AND OTHER FORMATS 36 (1998). See also KAGAN, *supra* note 89, at 42 (psychological constructs “are theoretical inventions intended to explain behavior. They are not ‘things in the brain.’”).

²⁴¹ The definition of a “psychological representation” is itself the subject of extensive dispute in the fields of psychology, linguistics, and philosophy. See, *e.g.*, Gregory McCulloch, *Mental Representation and Mental*

IV. NORMS AND NEURONS: TOWARD INTEGRATING BRAIN-LEVEL AND SOCIAL-LEVEL APPROACHES IN CRIMINAL LAW

At the start of this Article, I argued that similar beliefs have been at work in each of the past major criminal law and neuroscience movements and inform some of the current work that identifies the commission of violent offenses as emerging from brain-based pathology. This Part will unite past and current movements by exploring their common themes. It will then offer examples of how neuroscience could contribute to legal understandings of the causes of violent acts; these examples suggest an approach to incorporating neuroscience into criminal law that is less ambitious than a total brain-based theory of violence – but that may, for that very reason, prove more productive. Scholars like Elizabeth Phelps and Dame Susan Greenfield (among many others) examine the ways that beliefs and identities are formed on a neurological level; how people differentiate in-groups and out-groups; and how people use different kinds of emotions, like disgust, in making judgments about others. This work could inform approaches to the design of legal institutions to enhance pro-social behavior and reduce violent conflict, but they would not promise to provide clear answers “in the brain” for why violence happens.

The ideas at the end of this section are meant to be suggestive, not exhaustive, as there are many promising areas of collaboration, including those yet to be devised.

A. Uniting the Three Tenets

Understanding criminal violence primarily as brain-based rests on the notion that personal, social, and cultural phenomena – from an individual’s actions to the way markets function – not only can be explained, but are caused and determined, by the make-up of the most basic physical components of a system. This is reductive materialism,²⁴² a way of thinking that

Presentation, in LOGIC, THOUGHT & LANGUAGE 22, 22-23 (Anthony O’Hear ed. 2002) (describing definitions of a “psychological representation” across several intellectual disciplines).

²⁴² Calling this approach reductive is no slur – a majority of neuroscientists share a commitment to reductive materialism. Indeed, Michael Gazzaniga, a preeminent neuroscientist who coined the phrase “cognitive

aims to explain higher-level phenomena completely in terms of their lower-level components; it entails the belief that higher-level phenomena also are completely caused by lower-level phenomena.²⁴³ Thus, according to a reductive materialist view of the brain (“neuropsychological reductionism” or neuroreductionism²⁴⁴), all “human thought and behavior” is best understood by examining “physical processes taking place inside the brain[.]”²⁴⁵

Describing this school of thought, Professor Owen Jones writes:

[A]ll choices emerge from the human nervous system. ... The [nervous] system is composed of molecules, in turn composed of atoms, and it is driven by chemical reactions and electrical circuits. The nervous system and its brain are therefore part of a material world in which present events are caused by prior events, *extending back to the beginning of time and matter*.²⁴⁶

Those who subscribe to the strong reductionist position believe (or would agree) that the Big Bang contained within it all the information that has determined everything that has come after – “that the entire history of the stars [and] ... the history of life as well ... [was] immanent in that millionth of a second when the universe began,”²⁴⁷ including, among other things (or among everything) the emergence of life on earth, the evolution of human kind, and whether a particular person would commit a violent criminal offense. This is because “all choices emerge” from an unbroken chain of causation stretching back to “the beginning of

neuroscience,” identifies reductionism (or reductive materialism) as the dominant mode of inquiry in this field and one with great investigatory and explanatory power. See Snead, *supra* note 10, at 1278 (quoting Gazzaniga).

²⁴³ *Id.* at 1278 (citing PATRICIA SMITH CHURCHLAND, BRAIN-WISE: STUDIES IN NEUROPHILOSOPHY 20-21 (2002) (“a reduction has been achieved when the causal powers of the macrophenomenon are explained as a function of the physical structure and causal powers of the microphenomenon.”)).

²⁴⁴ Chorover, *Violence: A Localizable Problem?*, *supra* note 215, at 266.

²⁴⁵ *Id.* See also, e.g., THE CAMBRIDGE DICTIONARY OF PHILOSOPHY 599-602 (1995) (defining materialism as the premise that only physical things exist and therefore that all phenomena must be explained in terms of material causes). For a fine comment exploring the implications of reductive materialism in criminal law, see Andrew E. Lelling, Comment, *Eliminative Materialism, Neuroscience and the Criminal Law*, 141 U. PA. L. REV. 1471 (1993).

²⁴⁶ Jones, *supra* note 122, at 93 (emphasis added).

²⁴⁷ RICHARD C. LEWONTIN, BIOLOGY UNDER THE INFLUENCE 16 (2007) (critiquing the strong reductionist position).

time.”²⁴⁸ Translating this view to the relationship between brain, behavior, and society to understanding criminal violence leads to an individualistic approach in which the individual brain or even sub-regions of the brain are taken as the basic unit of analysis.²⁴⁹

Viewing criminality as the result of brain dysfunction – of biological difference between law-breakers and non-lawbreakers – dovetails with the concept of alterity. “Alterity” is the construction of community through the identification and exclusion of the Other.²⁵⁰ Criminal law, a strongly normative discipline, is understood to reinforce community ideals by defining and excluding that which threatens the community, whether the threat is practical, normative, or both;²⁵¹ thus alterity is a significant concept within criminal law. The relationship between criminal law and alterity is at best an ambivalent one, however, because it is an aspiration (and perhaps a conceit) of liberalism that we judge the act and not the actor.²⁵² Accordingly, the normative criminal law in the liberal state is both prone to alterity and on its guard against it. The idea of the biological Other, the “born criminal,” satisfies the urge to alterize the criminal but also raises questions about the propriety – and relevance – of doing so in a system that at least aims to judge acts and not statuses.

²⁴⁸ Jones, *supra* note 122, at 93. Cf. Patricia S. Churchland, *Moral Decision Making and the Brain*, in NEUROETHICS, *supra* note 19, at 3, 5-6 (describing the brain as a causal machine but noting that, due to its nature as a “complex . . . dynamical system,” it may defy prediction; arguing that unpredictability does not arise because activity in the brain exists outside of physical causes but because causation is not simple in systems of this type).

²⁴⁹ Individualism is used here in the sense of taking the individual as ontologically prior to the social (“methodological individualism”). See, e.g., LARS UDEHN, *METHODOLOGICAL INDIVIDUALISM: BACKGROUND, HISTORY, AND MEANING* 321 (2001), not the more general sense of “the assertion of one’s own will or personality,” AMERICAN HERITAGE DICTIONARY 656 (2d ed. 1991). See also Chorover, *Violence: A Localizable Problem?*, *supra* note 215, at 264 (arguing that the psychointerventionists, like lobotomists, made the error of looking at individual brains in isolation for the solutions to social problems).

²⁵⁰ Raymond Corbey & Joep Leersson, *Studying Alterity: Backgrounds and Perspectives*, in ALTERITY, IDENTITY, IMAGE iv (Raymond Corbey & Joep Leersson eds., 1991) (describing alterity and its role in societies’ self-definition).

²⁵¹ Paul Robinson, *Why Does Criminal Law Care What the Layperson Thinks Is Just? Coercive Versus Normative Crime Control*, 86 VA. L. REV. 1839, 1840 (2000) (“[t]he extent of criminal law’s moral authority determines the extent of its ability to shape community norms and to influence people’s conduct through normative forces”).

²⁵² Dan M. Kahan, *The Secret Ambition of Deterrence*, 113 HARV. L. REV. 413, 415 (1999).

Neuroscience approaches to legal issues can (but need not) feed into the concept of alterity in criminal law by defining people who commit crimes as biologically different.

Alterity in past and current claims about violent offenders is not subtle. For Cesare Lombroso, the brain of the criminal resembled that of the “rat” or the “lower carnivore.”²⁵³

Psychointerventionists of the mid-twentieth century compared violence in people to the behaviors of the “raging bull” or the “predatory and vicious lynx” and “wolverine.”²⁵⁴ The racial dimension present in past episodes also speaks to the notion of the violent person as the biological Other. As discussed above, Drs. Mark, Ervin, and Sweet explicitly linked their localization theory of violence – and their recommendation of mass lobotomy – to putative neurobiological differences in race rioters. The absence of any consideration of the neurobiology of white violence toward African-Americans suggests that they *ex ante* viewed their subjects (however subconsciously) as Other.

The express and implied racism of earlier criminal law-brain science movements emphatically is not present in current work in the field. Scholars are extremely careful to distinguish their work from the race-based premises and applications of brain sciences in criminal law in past eras.²⁵⁵ Further, none of the current work focuses on racial difference, nor have any scholars differentially focused on any racial groups. Absent the racial dimension, however, alterity remains implicit in current claims that locate criminal violence in brain

²⁵³ See discussion of Lombroso’s work *infra* at Section I.A.2. For a comprehensive treatment of scientific racism, focusing particularly on brain difference, see generally Gould, *supra* note 54. For another excellent critique of past scientific racism by a leading biologist of violence, see DEBRA NIEHOFF, *THE BIOLOGY OF VIOLENCE* 2-20 (2002).

difference: If behavior is determined by brain structure and function (holding aside for the moment the causes and fixity of such difference), and a person behaves in ways that deviate from the norm, then that difference must be biological difference; this makes the offender the Other.

In constructing violence as a biological feature of violent offenders, historical and some modern localization stories offer a comforting answer to the problem of evil: There are no evil people, just dysfunctional brains. One of the most common reactions to horrific acts of violence is to ask how a person (or people) could do such a thing. Extreme acts of violence are, most of the time and to most people, incomprehensible. Such acts pose hard questions. Perhaps the only easy or comforting answer is that such acts are the product of real, literal sickness: “Crime is ... pathological”;²⁵⁶ “Crime [is] a disease.”²⁵⁷

B. Turning the Premises Around: Toward Integrating Norms and Neurons

The criminal law’s resurgent attention to neuroscience offers an opportunity for collaboration that does not recapitulate past problems rooted in determinism and alterity. While accepting that all behavior is produced by the brain,²⁵⁸ work of the kind discussed here explores how the criminal law could use this knowledge at levels ranging from the individual to the general, and to clarify the contributions of both pathology to normalcy to the commission of violent offenses. Two areas of inquiry, below, on in-group/out-group biases and on the role of emotions in decision-making, suggest that neuroscience research can help illuminate the presence of basic neural systems that become socially shaped; this suggests that the law may not be able to eradicate the sometimes dangerous predispositions that arise from these systems but

²⁵⁶ MCCORMICK, *supra* note 73, at 560.

²⁵⁷ Kirchmeier, *supra* note 4, at 631.

²⁵⁸ Reflexes still may be observed in the absence of any functioning brain other than the brain stem, as in infants born with anencephaly; reflexes, though, are not “behavior.” *See, e.g.*, C.P. PANTELIADIS, B.T. DARRAS, *ENCYCLOPEDIA OF PEDIATRIC NEUROLOGY* 367 (2000) (describing reflexes in anencephalic infants).

could leverage them in more useful ways. This section closes with some suggested avenues for future research.

1. *In-Groups & Out-Groups, Identity, and Violence*

“Why can’t we all just get along?”²⁵⁹ Rodney King uttered this famous plea when riots rocked Los Angeles after an all-white jury acquitted police officers of severely beating Mr. King. Mr. King’s question is a perennial one, as is the problem of inter-group violence and subjugation. Recent cognitive neuroscience studies suggest that people are primed to make self-other distinctions²⁶⁰ – but that who we see as “self” and who we see as “other” are strongly socially influenced²⁶¹ as well as subject to change through experience and learning.²⁶²

Because much violence involves inter-group conflict, as well as conflict between individuals of perceived different groups, scholars in criminal law may look to the developing neurobiological literature on in-group/out-group identification, belief, and identity to reduce destructive group bias and conflict.²⁶³ It is unlikely that there are distinct brain-based predispositions or pathologies subserving all the violent offenses from hate crimes to gang behavior to terrorism to ethnic and political violence; yet, self/other and in-group/out-group distinctions may play some role in all of them. Functional imaging studies show that fear conditioning is easier to establish and harder to erase relative to members of the “other” group

²⁵⁹ A videotape of King’s statement is available at <http://www.youtube.com/watch?v=aMfr2CgIPhg>.

²⁶² See, e.g., Mary E. Wheeler & Susan T. Fiske, *Controlling Racial Prejudice: Social-Cognitive Goals Affect Amygdala and Stereotype Activation*, 16 *PSYCHOL. SCI.* 56, 56 (2005) (fMRI study showing that in-group/out-group perception is changed based on task – race can be salient in the default condition, but subjects will quickly reorganize in-group/out-group based on instructions to attend to age, gender, or the presence of differently-colored dots on photos of strangers’ faces).

²⁶³ While work on the neuroscience of group bias has not yet been applied within criminal law scholarship, it has been applied to general questions of institutional design, see, e.g., Goodenough, *Institutions, Emotions and Law*, *supra* note 18, and Hill & O’Hara, *supra* note 16.

than to one's own group: Subjects in the lab learn positive associations faster and negative associations more slowly as to members of their own groups; conversely, negative views of the members of the "other" group persist much longer than toward members of one's own group, even in light of contrary information.²⁶⁴

This work on the difference between us/them perception raises the question of how these beliefs come to be incorporated physically by the subject²⁶⁵ – and how these kinds of beliefs may relate to acts of violence. Examining how beliefs come to be laid down in the brain, researchers are finding that ideas with a belief-based component are both easier to remember and harder to overcome than ideas communicated through fact or logic.²⁶⁶ Everyone has experienced that strong emotion ("high arousal") makes a much stronger mark in one's mind than dry facts; this metaphorical sense appears to be literally true in fMRI studies of belief and memory formation.²⁶⁷ One's basic beliefs appear to become encoded into the brain through a combination high-arousal experiences and through repetition.²⁶⁸ Institutionalized religious practices incorporate both of these features, with emotional stories and ceremonies (high arousal), and prayers, memorization of texts or creeds, and chanting (high repetition).

There may be a relationship, Dame Susan Greenfield speculates, between the degree of individualism of a person's identity and the degree autonomic arousal and aversion the person will feel in response to threats or risks to self.²⁶⁹ A person with a more collective identity

²⁶⁹ Greenfield, *supra* note 267.

may perceive threats or insults to the group more like a threat to the self; conversely, he or she may perceive a risk to the self that does not implicate the group as less comparatively alarming or aversive.²⁷⁰ If religion were used to inculcate collective-focused beliefs, through high-arousal experiences and repetition, such beliefs would be difficult to dislodge through appeals to fact, logic, or self-interest. This work does not suggest that some cultural beliefs predispose any person to violence. But it may suggest that people from cultures that promote group identification will perceive threats or slights to the culture as if directly to the individual; they also may be more willing to take individual risks on behalf of the cultural group.²⁷¹

Greenfield's description of how neural processes mediate and are mediated by cultural processes may not provide an explanation for why some people become suicide-terrorists: Not only does she recognize the attenuated relationship between belief and identity, and identity and risk perception, but also the large leap from reduced individual risk aversion to committing self-destructive violence. Further, her remarks are speculative and require much additional investigation. But her approach offers a plausible account of why suicide-terrorism, or other self-destructive ways of perpetrating group or political violence, like the Japanese tokubetsu kōgeki tai (kamikaze), appear more commonly in cultures that expressly value strong religious or national identification.

This way of relating neuroscientific findings to individual violent crimes notably does not conform to the three themes or tenets that have run through prior criminal law-brain science movements: It does not posit any putative violence-related brain dysfunction in the perpetrator; does not view violence as a thing that can be localized to a specific part of the brain; and, although it explores how cultural differences may relate to individual behavior, does not

²⁷⁰ *Id.*

²⁷¹ *Id.* (in Greenfield's more colorful formulation, "you can self-destruct and it does not matter").

construe the perpetrator of a violent act as essentially different from people who do not commit such acts. Further, under this view, it would not be possible to put an individual into a scanner, identify an under- or over-active brain region, and then use such a scan as a prediction technique of future violent conduct in the pre- or post-conviction setting. Rather, it construes violence of a specific type as the end of an array of interactions between brain, culture, and political context, and explores how those factors relate to individual responses to risk to the self; in other words, such studies on belief formation show how neurons and norms literally come together.

2. *A Few More Avenues*

There are myriad ways neuroscience could contribute to criminal law, ranging from general models of emotion and behavior to specific analyses of particular punishments and rehabilitation strategies. In such a new and developing field, it would be impossible (as well as an act of hubris) to try to predict all of the potential avenues of research. A few of these future avenues could include work on preventing criminal behavior, designing individual sentences and general penalties in a more informed manner, and rehabilitating offenders.

As a threshold matter, it could be useful to investigate the non-pathological pathways that lead to violence, like confinement and frustration. The existence of “air rage” and “road rage” suggest that there are situations or structures that predictably stress people beyond their capacity for self-control. If we were to understand better the general conditions that provoke aggression, we might be able to design systems that help minimize such triggers. This moves us from the notion of violence-as-pathology to a more general understanding of our capacity for violence under given conditions.

Neuroimaging could perhaps help describe what types of behaviors or beliefs that lead to violence are more readily changeable or malleable. When experimental psychologists

teach an animal a conditioned response – like the expectation of a reward in response to a tone – and then teach the animal to “unlearn” that response, they call it “extinguishing” the response.²⁷² What neurobiological factors make certain behaviors or beliefs easier or hard to “extinguish”? And how would that vary based on individual factors, like motivation? Conversely, there may be some behaviors that may be particularly resistant to change. In both cases, such information might have predictive value as to recidivism as well as suggest which offenders would benefit most from rehabilitation strategies.

Another area may be juvenile justice. As the landmark decision in *Roper v. Simmons*,²⁷³ recently acknowledged in holding unconstitutional the death penalty for offenders who committed their offenses as juveniles, research shows that different parts of the brain mature at different ages.²⁷⁴ While the Court focused on the “diminished culpability of juveniles,”²⁷⁵ this research also raises the question of whether juveniles are more amenable to rehabilitation than adults. If so, that would suggest a reconsideration of the punitive emphasis in much of the juvenile system. Further, it might be possible to model effects of punishment on juveniles on a neurological level: What are the effects on developing brains of being exposed to conditions of punishment, and do those differ from effects on adult brains?

The neurological impact of conditions of confinement could be investigated as well. It is well known observationally that extended solitary confinement seriously affects mental health.²⁷⁶ Hypothetically, if it could be determined that extended solitary confinement

causes neurological changes known to be associated with severe stress and with certain mental illnesses, like cell death in the hippocampus, that might provide grounds to set limits on certain conditions of confinement. This would move out of research on the causes of violence by individuals, but would consider whether the state does undue violence through methods of punishment.

* * *

Albert Einstein wrote that the best models should be “as simple as possible, but no simpler.”²⁷⁷ The claim that the criminal law can understand violence principally as emerging from localized brain dysfunction in people who are neurobiologically distinct is simpler than possible. The brain is a physical manifestation of the interaction between biology and society; our increasing understanding of its plasticity and function may lead us to conclude that it is impossible to fix a biological nature apart from a social existence. A “more unified picture of brain-behavior relationships and [of] the nature of human problems” would integrate “the overlapping aspects of existence represented by the organization of the brain, the individual, and the society.”²⁷⁸ The challenge in this time period, in this particular episode of the affair between criminal law and neuroscience, is to use neuroscience not to craft attractive simplifications but to shed a measure of light on complex and multi-faceted realities.
